Except for Paul Pimsleur, little or no empirical research with students who exhibited L2 learning problems or students classified as LD prior to the 1990s had been conducted. Since that time, Sparks and Ganschow have conducted numerous studies that have found strong connections between students' L1 skills and their L2 aptitude, L2 oral and written proficiency, and L2 classroom achievement. These studies have compared (a) high- and low-achieving L2 learners, (b) low-achieving L2 learners and L2 learners classified as LD, and (c) students classified as LD who passed L2 courses and LD students who received course substitutions and waivers for the LD requirement. (For a comprehensive review of studies cited here, see Ganschow & Sparks, 2001; Sparks, 2006; Sparks, Humbach, & Javorsky, 2008.)

In studies that have compared high- and low-achieving L2 learners enrolled in L2 classes, findings have shown that high-achieving L2 learners exhibit significantly stronger L1 skills in, for example, word reading, pseudo-word decoding, spelling, writing, grammar, and in L2 aptitude on the Modern Language Aptitude Test (MLAT) than low-achieving L2 learners, even after controlling for differences in cognitive ability. In most studies, the primary L1 difference was found on measures of phonological processing, that is, speech sounds and sound-symbol relationships. In other studies, high- and low-achieving L2 learners who displayed stronger L1 skills and higher L2 aptitude also achieved higher levels of oral and written L2 proficiency. In recent longitudinal studies, L1 skill differences in reading and language between high- and low-proficiency high school L2 learners have been found to emerge as early as the primary grades (Sparks et al., 2009a).

Studies that have compared low-achieving (non-LD) high school L2 learners with students classified as LD enrolled in L2 courses have found that there are no cognitive (IQ), L1 achievement (e.g., reading, spelling, vocabulary), or L2 aptitude (MLAT) differences between these two groups. In recent studies that followed students over several years, no significant differences were found in early L1 literacy skills, cognitive ability, L2

aptitude *as well as* L2 oral and written proficiency, L2 word decoding, L2 spelling, and L2 classroom achievement among low-achieving learners and LD students in L2 classes.

In a series of studies with postsecondary learners, students classified as LD were divided into groups defined by whether or not they exhibited IQ (aptitude)-achievement discrepancies. The findings revealed no differences in college entrance exam scores, L2 aptitude (MLAT), college L2 grade point average (GPA), or graduating college GPA between the discrepancy-defined groups. (In the United States, course substitutions and waivers for students classified as LD are commonplace [Sparks, 2008].) When LD students who had received course substitutions for or waivers from the college L2 requirement were compared with LD students who had passed college L2 courses, no differences were found in IQ, academic achievement (reading, writing, language, math), graduating GPA, and ACT/SAT scores, or on demographic variables (e.g., tutoring in the L2, time of LD diagnosis). Moreover, L2 course grades for those LD students who had completed L2 courses in high school and college were primarily A, B, and C, which showed that students classified as LD often do well in L2 courses. (In the United States, grades range from highest [A], to average [C], and lowest [F].)

The aforementioned findings in relation to LD students are important because they show that students classified as LD (a) do not routinely exhibit problems with L2 learning, (b) do not exhibit L1 skill or L2 aptitude differences or more severe L2 learning problems than other low-achieving L2 learners, and (c) do not exhibit distinct learning profiles or unique problems with L2 learning when compared to students classified as LD who have succeeded in L2 courses. The findings suggest that like all other academic skills, L2 aptitude and L2 proficiency occur along a continuum of very strong to very weak language learners and that L2 learners classified as LD, like non-LD learners, are represented along this continuum.

Research on L2 Teaching Strategies

Despite the growing body of evidence that L2 learning is strongly related to students' L1 skills, L2 teaching strategies for students classified as LD and low-achieving L2 learners have focused primarily on non-cognitive variables such as affect, learning styles, learning strategies, and personality (see Ehrman, 1996). However, Sparks and Ganschow have argued that low-achieving L2 learners have a cognitive difference (or deficit) that is reasonably specific to *language* skills (Sparks, 1995; Sparks & Ganschow, 1995). Their studies have shown that students' anxiety about or motivation for L2 learning are related to their levels of L1 learning skills and L2 aptitude, both of which have been found to be predictive of oral and written L2 proficiency and achievement (Sparks & Ganschow, 2007; Sparks et al., 2009b). To date, well-designed studies using non-cognitive variables to teach L2s have not produced evidence showing that lowering anxiety, increasing motivation, using learning strategies, teaching to individual learning styles, and matching instruction with personality have significantly improved the L2 proficiency of low-achieving L2 learners, LD or otherwise. (For differing points of view on non-cognitive variables and L2 learning, see MacIntyre, 1995, and Sparks & Ganschow, 1995.)

However, evidence has shown that instruction in language skills can be effective in teaching L2s to low-achieving learners and students classified as LD. For example, Demuth and Smith (1987) developed an experimental course for at-risk university students that emphasized explicit instruction in language structure, particularly grammar and contrastive analysis of students' L1 and their L2. More recently, Downey and Snyder (2001) reported success with a modified L2 program in Italian, Spanish, and Latin for postsecondary students in which direct instruction in language skills was provided.

In order to teach low-achieving and LD students, L2 researchers and L2 classroom teachers could examine research related to L1 reading, which has shown that the teaching of reading is best accomplished by directly teaching domain-related skills, that is, skills related to reading (Vellutino, Fletcher, Snowling, & Scanlon, 2004). Likewise, direct teaching of other language skills, for example, grammar, and vocabulary, are domain related because they teach skills related to language. Both L1 and L2 researchers have suggested that the fundamental competencies in reading—decoding and comprehension—are the same in both L1 and L2 reading (e.g., see Koda, 2007; Sparks, 2009). In a recent longitudinal study, half of the variance in high school students' L2 decoding and spelling skills was explained by their L1 decoding and spelling skills in elementary school, and 40% of the variance in L2 reading comprehension was accounted for by L2 decoding skills (Sparks, Patton, Ganschow, Humbach, & Javorsky, 2008). Other recent studies have found evidence for long-term cross linguistic transfer of L1 skills in elementary school to L2 skills in high school (e.g., Sparks et al., 2009a, 2009b).

To teach domain-related skills, some educators have suggested that L2 instruction for low-achieving and LD learners can best be provided through a structured language approach that has been found to be helpful in teaching at-risk and low-achieving students to read and spell their L1 (Sparks, Ganschow, Kenneweg, & Miller, 1991). In this method, the teacher initially introduces the sound-symbol correspondences in the L2. As students learn the sound-symbol system of the new language, the sounds are combined to form words. Grammatical rules are presented one at a time in structured exercises. A daily lesson plan is used and lessons are carefully sequenced from those with simple to increasingly complex sound-symbol relationships and rule systems. The L2 teacher coordinates this teaching approach with a regular L2 curriculum. The primary reasons for using this teaching method are that the lessons (a) focus on the *direct* teaching of language skills in the L2; and (b) teach skills that involve the primary areas of weaknesses in the students' L1, that is, phonology and grammar. Empirical studies using this approach have shown that (a) low-achieving L2 learners, including L2 learners classified as LD, significantly increased their L1 skills and L2 aptitude (MLAT) scores over one to two years of L2 instruction; and (b) low-achieving L2 learners (including LD students) in high school taught by this approach in Spanish over two years exhibited no differences in L2 proficiency (reading, writing, listening, speaking) when compared to high-achieving L2 learners taught using traditional L2 instruction (Sparks et al., 1998). These findings suggest that direct instruction in language skills has the potential to improve L2 learning for low-achieving and LD learners in L2 classes.

Conclusion

More empirical research for teaching L2s to low-achieving learners is needed. The paucity of research on teaching methods for students with L2 learning problems is due, at least in part, to the adoption of policies by secondary and postsecondary institutions that allow students classified as LD to obtain waivers from or course substitutions for the L2 requirement. These policies suggest to L2 educators that there is something different about the L2 problems of students classified as LD. Yet, evidence has shown that there are no cognitive, L1 achievement, or L2 aptitude differences between low-achieving L2 learners and students classified as LD enrolled in L2 courses; classification as LD is irrelevant as to whether students will exhibit problems with L2 learning; and explicit teaching of L2 language skills to low-achieving and LD learners will benefit both groups.

Forensic Discourse Analysis

LORNA FADDEN

Introduction

Diverse areas of criminal and civil investigation and law have benefited from discourse analysts' research and its practical applications. Covert police recordings can be analyzed for manipulation (Shuy, 2005), suicide notes can be verified for authenticity (Shapero, 2011), question and answer sequences in police interviews are scrutinized to demonstrate how much evidence is produced by investigators and how much by suspects (Hill, 2003), power imbalances are addressed illustrating the conversational disadvantage for suspects and witnesses (Heydon, 2005), true and false confessions are distinguished (Kassin & Gudjonsson, 2004), defamation lawyers consult linguists to prove or disprove malicious intent (Shuy, 2010), contracts (Stygall, 2010) and product instructions and warnings (Shuy, 2007) are assessed for communicability and clarity. In these and other areas, forensic linguists have applied the descriptive techniques of discourse analysis to address three dimensions: what speakers/writers say, what audiences/readers hear, and the role that context plays in the interpretation of the message.

The domain of discourse analysis itself is vast and linguists describe naturally occurring language (as opposed to the constructed examples that often form the basis of study in syntax and semantics) in order to explain the constructions and conventions that underlie communicative practice. The broader areas in forensic discourse analysis touch on speech acts (Austin, 1962; Searle, 1969), speakers' cooperation (Grice, 1975), turn taking (Sacks, Schegloff, & Jefferson, 1974), coherence and cohesion (Halliday & Hasan, 1976), and institutional discourse (Drew & Heritage, 1992). To demonstrate the application of discourse analysis to answer forensic questions, four areas are highlighted: given and new information, narrative analysis, topic attribution, and ambiguity resolution.

Example Analysis I: Given and New Information

As part of a decades-old battle to exonerate Derek Bentley of the 1952 murder for which he was convicted and executed, Malcolm Coulthard examined statements Bentley made to police upon his arrest (Coulthard & Johnson, 2007, pp. 173–80). Bentley, who was 19 years old, and his friend, 16-year-old Christopher Craig, were caught in the middle of an attempted burglary on the roof of a London warehouse. Bentley had already surrendered to police when Craig shot two officers, wounding one and killing the other. Despite Bentley's being unarmed, both were found guilty of murder. Craig was handed a life sentence as he was under 18, while Bentley was sentenced to death.

In order to convict Bentley of murder, the prosecution in part needed to demonstrate that Bentley at least knew that Craig had a gun. His alleged knowledge of the weapon was supported by the 44-sentence statement taken by police, sworn to be Bentley's own, unaided narrative. Sentence numbers reflect those in the original statement.

2 FORENSIC DISCOURSE ANALYSIS

- (21) We hid behind a shelter arrangement on the roof.
- (22) We were there waiting for about ten minutes.
- (23) I did not know he was going to use **the** gun.
- (24) A plain-clothes man climbed up the drainpipe and on to the roof.
- (25) The man said: "I am a police officer – the place is surrounded." (Coulthard & Johnson, 2007, p. 175)

Highlighting the importance of this passage to the jury, the judge made much of the determiner "the" to modify "gun." He reasoned that if the first mention of the gun had been paired with indefinite determiner "a," then it might be argued that Bentley did not know about it. However, the specificity of the noun phrase in "I did not know he was going to use *the gun*" was enough to assert that Bentley did indeed know of it. In other words, because the gun was revealed as given information (*the gun*), as opposed to new, or otherwise unspecified (*a gun*), Bentley had to have had a specific gun in mind. In the interview, however, "the gun" would have been given information between the interlocutors, and line 23 then, was most likely produced in response to a question from police. (See Gundel, Hedberg, & Zacharski, 1993, for a discussion of givenness.)

Later in the statement, Bentley appears to contradict himself by claiming not to know that Craig had a gun. This contradiction would be used to discredit his account of the events.

- (39) I knew we were going to break into the place.
- (40) I did not know what we were going to get – just anything that was going.
- (41) I did not have **a gun**, and I did not know Chris had one until he shot. (Coulthard & Johnson, 2007, p. 175)

That Bentley first said that he did not know Craig would use the gun (23) presupposes that Craig did indeed have a gun that Bentley knew about. The contradiction obtains in (41) when Bentley said that he did not know that Craig had one until Craig used it. This contradiction damaged Bentley's credibility.

Example Analysis II: Narrative Analysis

Narratives represent series of events told by one individual, often chronologically, comprising a longer turn, progressing uninterrupted by other participants, except perhaps for back channels. Broadly speaking, a narrative is composed of a background or orientation for the events, any actions, reactions, and complications, and a conclusion (Labov & Waletzky, 1967). Narratives are composed of events and states that manifest, and do not ordinarily include events and states that do not manifest, unless there is good reason to do so, a principle that Coulthard applies to demonstrate problems in Bentley's narrative. Again, sentence numbers represent those in the original statement.

- (6) A little later Norman Parsely and Frank Fasey called.
- (7) **I did not answer the door or speak to them.** (Coulthard & Johnson, 2007, p. 177)

The negative in (7) is warranted because responding to a caller at the door is the expected action. Because that is not what occurred, it is worth noting in the narrative. Negatives appear elsewhere in Bentley's statement, but without being reasonably linked to the surrounding discourse.

- (16) Chris then climbed up the drainpipe to the roof and I followed.
- (17) Up to then **Chris had not said anything**.
- (18) We both got out on the flat roof at the top.
- (26) He caught hold of me and as we walked away Chris fired.
- (27) **There was nobody else there** at the time.
- (28) The policeman and I then went around the corner by a door. (Coulthard & Johnson, 2007, p. 177)

Nothing in the prior discourse supports the need to report that Craig *had not said anything* (17), nor that no others were present (27). In any situation, there is “an infinite number of things that did not happen and thus the teller needs to have some special justification for reporting any of them to the listener, in other words there must be some evident or stated reason for them being newsworthy” (Coulthard & Johnson 2008, p. 176). In these cases, the negative elements likely result from a question or assertion posed by police collecting the statement. Coulthard concludes therefore that Bentley’s account of what happened was not a narrative in the truest sense, but created out of dialogue between Bentley and the investigators, as their questions and assertions led him to provide details of evidentiary importance, then converted into monologue form.

Bentley received a posthumous pardon on July 30, 1998, and the case remains a landmark in forensic linguistics because language evidence was used both to convict Bentley, and to exonerate him.

Example Analysis III: Topic Attribution

When gathering evidence, investigators may covertly record suspects’ speech. Assuming that incriminating topics arise in the recordings, they must be clear and they must be attributed to the right speaker in order to be forensically useful. The case of *Texas v. T. Cullen Davis* relied heavily on one such covert recording where at trial, Roger Shuy testified for the defense regarding what was said and who produced the damning words (Shuy, 2005). Davis had been charged with the 1976 murder of his wife’s lover and her daughter. The wife, Priscilla, survived the shooting, and Davis was later charged with soliciting the murder of her and the judge overseeing their divorce, a man with whom he believed she had become intimately involved. Davis would be acquitted after three trials.

During the investigation, one of Davis’s employees, David McCrory, told police that not only had Davis confessed to him that he was responsible for the deaths, but that Davis also ordered him to arrange the murders of Davis’s wife and the judge. McCrory cooperated with police, and wore a hidden recording device to capture the interaction shown below. Bracketed portions represent overlapping speech; italicized portions represent physical actions caught on video surveillance.

Davis
 I told him that, uh, to treat you like any
 other employee and, uh, so don’t give
 me too much pressure in that regard.
 I can’t, uh, say you’re gonna be gone
 a day or two every week or so.
(Davis gets out of the car and walks to the trunk)

McCrory

Well look, this fuckin’ murder business—

4 FORENSIC DISCOURSE ANALYSIS

You better—

alright,

[give me]

[give me]

a little

[noti-, advance notice

good [inaudible],

alright but I

[uh, you know]

[inaudible]

I got to have an alibi ready for Art when the-

When the subject comes

[up]

(Davis comes back to the front door of the car.)

So give me some advance notice,

warning.

(McCrory gets out of the car and leaves) (Shuy, 2005, pp. 46–7)

—is a tough son of a bitch.

Now you got me into this

[into this goddamn deal]

[right?]

[Now I got j-]

I got Judge Edison dead for you

I'll get the rest of them dead for you.

You want a bunch of people dead,

right?

[di-, di-]

Help me too,

[okay?]

Okay?

[alright]

I will.

I gotta go.

Shuy indicates that two different topics co-occur. Davis is talking about McCrory missing work and having to account for absences. McCrory is talking about the hit that Davis has allegedly placed on various individuals. In natural discourse, speakers tend to produce turns that are cohesive and that transition smoothly from one another. No such cooperation is evident in this sample. During the trial, Shuy used the side-by-side transcript as shown to demonstrate to the jury that each speaker maintained his own topic, neither addressing or responding to the other's. Furthermore, the key topic relating to the solicitation of murder was spoken by McCrory while Davis was outside of the vehicle. The "good" and "alright" on the transcript might appear to be Davis's concurrence with McCrory's explicit reference to "getting people dead"; however, "neither was uttered in a response intonation, but rather as low-pitch discourse markers related to his own topic" (Shuy 2005, p. 48).

When looking at the two streams of discourse, it cannot be argued that Davis himself said anything incriminating, nor that he agreed with any part of McCrory's topic. Moreover, we cannot be certain that Davis even heard McCrory because he was outside the car, and concurrently talking on his own topic. Shuy refers to this type of covert recording strategy as a "hit-and-run" where the cooperating witness produces the incriminating words for the recording in such a manner that the suspect is either unaware or unable to respond. For language to be incriminating, it must be both cohesive with surrounding discourse, and, if not from the mouth of the suspect, it must be evident that the suspect is in unambiguous agreement with what is said.

Example Analysis IV: Resolving Ambiguities

Defamation cases involve language that a plaintiff claims harms his or her image, or the image of a corporate identity. In some cases, however, it is not clear whether the alleged offending language is indeed defamatory. When the language in question is ambiguous, discourse analysts may be consulted to examine the context to help resolve what the speaker or author meant. A simple example of ambiguity and contextual resolution is shown:

- | | |
|--|---|
| 1 A: Nice hat.
B: Thanks! I just got it. | 2 A: Nice hat.
B: What's wrong with it? |
|--|---|

The nice hat example shows how the same words can be interpreted as delivering two different speech acts: (1) a compliment; and (2), an insult. Contexts, both social and linguistic, allow speaker B to interpret speaker A's utterance. If speaker A is otherwise being congenial, and expresses levity in her voice with higher pitch, B will know she has been paid a compliment. If speaker A is not otherwise congenial, or a sneer accompanies her utterance, B will know that A is insincere.

In defamation cases, where two sides are in dispute over the same language, "Linguists can analyze the discourse content in which the alleged defamation takes place, and sometimes even offer help about the difficult-to-prove requirement that the offending language contains actual malice or a reckless disregard for the truth" (Shuy, 2010, p. 31).

Speakers ordinarily leave little room for ambiguity or uncertainty and generally we adhere to the cooperative principle (Grice, 1975). When we violate the cooperative principle, we do so in order to achieve some conversational goal, such as when Speaker A is being insincere in (2). Should ambiguity or uncertainty arise, a repair is initiated, and either the speaker will self-correct unprompted, or the hearer will request clarification (Jefferson, 1974; Sacks, 1995). In a 1996 defamation case, Roger Shuy (2010) identifies ambiguities in a news broadcast that were exploited to lead viewers to conclude that Terri Stokes was responsible for murdering her husband, when in fact there had never been sufficient evidence to charge her.

In 1993, Dennis Stokes was shot and killed as he slept in his bed in his Minnesota home. Deputy Sheriff Tom Johnson led the investigation, and, as with many murder investigations, the victim's spouse was the first to come under suspicion. In fact, Stokes's wife, Terri, would turn out to be the only suspect, a point that had been raised repeatedly in media coverage of the case. Despite the intense focus on the victim's wife, the investigation did not uncover sufficient evidence linking her to the murder. At issue in this case was not that Terri was a suspect, but rather that Johnson had "singled her out" as the only one who could have committed the crime (Shuy, 2010, p. 60). In different broadcasts throughout the investigation, Johnson repeatedly states that Terri was the sole suspect—a statement that would be exploited later to paint a picture of certain guilt.

In an *American Journal* broadcast featuring the Dennis Stokes case, a reporter presents some of the details from the night of the murder. In an interview with that reporter, Deputy Sheriff Johnson expresses an ambiguity that was left unresolved, but owing to the repeated coverage in which he focuses on Terri as the only suspect, the only reasonable interpretation the audience can make links Terri to the crime.

- | | |
|-----------|---|
| Reporter: | The night of the murder, Terri had been sleeping at her brother and sister-in-law's, a half-hour away . . . Still, Investigator Johnson says Terri was alone downstairs, and might have secretly left the house during the night. |
| Johnson: | We don't have enough evidence to show, to prove that she did it beyond a reasonable doubt. I think we have a lot of reasons why. (Shuy, 2010, p. 60) |

On its own, Johnson's last sentence is ambiguous, possibly prompting the hearer to ask "why she did what?" But given that Johnson had been saying throughout the investigation that Terri was the only suspect, his "reasons why" can only be interpreted as the reasons why she killed her husband. The reporter made no effort to resolve this ambiguity, or even address another possible interpretation.

Later in the broadcast, the reporter exploits another ambiguity to the detriment of Terri's image. By this time, Terri had moved from Minnesota to Idaho, and a news team, accompanied by her former mother-in-law Joyce Stokes, carried out an "ambush interview."

- Reporter: Joyce Stokes was left with no answers to the questions she came all the way to Idaho to ask.
- Joyce: I don't know why she won't talk to me. If she's not guilty, why won't she talk to me? Why doesn't she tell me she's sorry? She won't do it.
- Reporter: You're one hundred percent sure that Terri killed Dennis.
- Joyce: One hundred percent. There is no doubt about it. (Shuy, 2010, p. 61)

Ambiguity arises in Joyce's "Why doesn't she tell me she's sorry?" As Shuy points out, an apology is a speech act acknowledging and accepting responsibility for an offense. On its own, Joyce's question could be pleading for an apology for Terri's not speaking with her mother-in-law, or it could be pleading for an apology for the murder of her son. The ambiguity, however, is resolved in two ways. First, the reporter has already established in this and earlier coverage that the central topic is Terri's likely guilt. Second, the reporter resolves Joyce's ambiguity by shifting the topic from talking to her former daughter-in-law, to seeking confirmation that Joyce believes that Terri is guilty of Dennis' murder.

Terri Stokes was never charged for the murder of her husband, nor was anyone else, and the crime remains unsolved. The media reporting of Johnson's narrowly focused investigation tried her for the crime nevertheless.

Conclusion

Scholars and practitioners working in the area of forensic discourse analysis call upon an "eclectic selection of tools and a developmental approach" when analyzing a forensic text (Coulthard & Johnson, 2007, p. 14). Finding theoretically grounded solutions to problems in a forensic text necessitates a broad and deep understanding of the field of discourse analysis, to give an understanding of what was said, what was heard, and the role of context. And as the examples above show, language evidence can be central to a criminal or civil matter.

Forensic Linguistics: Overview

NICCI MACLEOD

Broadly defined, “forensic linguistics” refers to the study of the interface between language and the law. Thus, there are two overarching areas of research and practice within the field: the linguistic study of legal texts and processes, sometimes referred to as “language of the law” or “language and law,” and the provision of linguistic evidence in criminal and civil cases, sometimes referred to as “forensic linguistics” narrowly defined.

Authorship Analysis

The term “forensic linguistics” is generally accepted to have come into being with the publication in 1968 of Jan Svartvik’s *The Evans Statement: A Case for Forensic Linguistics*. There, he analyzed four statements that Timothy Evans, executed in 1950 for the murder of his baby daughter, was alleged to have made following his arrest. Using both qualitative and quantitative methods Svartvik demonstrated considerable stylistic discrepancies between the statements, thus raising serious questions about their authorship. Questions of authorship remain one of the central concerns of forensic linguists to this day. As well as offering a sociolinguistic profile of an author, linguists are often requested to comment on the likelihood of an individual having authored a particular text, with techniques for identifying valid and reliable style markers subject to ongoing debate and development (Chaski, 2001; Grant & Baker, 2001; McMenamin, 2001).

Perhaps the most well known example of the use of linguistic authorship analysis in a criminal context is that of the Unabomber. Between 1978 and 1995, a number of letter bombs were sent to targets across the United States, many of them universities and airlines. In 1995, a letter was sent to the *New York Times* promising that the bombings would stop if the paper agreed to publish the sender’s manifesto. The 35,000-word manifesto, “Industrial Society and its Future” was published jointly by the *Times* and the *Washington Post* in late 1995. Shortly afterwards, a man named David Kaczynski, having read the manifesto and compared it to earlier writings of his brother Ted, became convinced his brother was the author and alerted the FBI. After a raid on Ted Kaczynski’s remote log cabin in Montana, FBI agents recovered a number of documents that had been authored by Kaczynski, which they subjected to linguistic analysis. Particular words and phrases were identified that appeared in both the manifesto and Kaczynski’s other writings, and it was these similarities that formed the basis of the FBI’s claims that Kaczynski was the Unabomber. Although they were challenged by the opposing expert at Kaczynski’s trial on the basis that the words and phrases in question were quite common, and to be expected in persuasive writing—items such as *at any rate*, *in practice*, and *on the other hand*—the FBI were able to demonstrate with the use of an Internet search engine that, while frequent in isolation and in combinations of two or three, the only search returns on documents containing *all* the items were online versions of “Industrial Society and its Future.” The case thus provided an “illustration of the consequent forensic possibilities that idiolectal co-selection affords for authorship attribution” (Coulthard, 2004).

The matter of authorship has also been key in overturning convictions that have occurred as a result of miscarriages of justice where, like in the Evans case, there are suspicions that

2 FORENSIC LINGUISTICS: OVERVIEW

incriminating documents have been partially or wholly fabricated, or the origins are at any rate not what the police originally claimed them to be. Examples include Derek Bentley, the Bridgewater Four, and the Birmingham Six (see Coulthard & Johnson, 2007).

As well as ransom notes, suicide notes, threatening letters, police statements, and the like, practitioners in the field have found themselves required to comment on the likely author of texts from increasingly diverse domains of language use, including Internet relay chat and mobile phone text messaging, as technology has progressed. These issues are discussed in HISTORY OF FORENSIC LINGUISTICS.

Plagiarism

A related area that has interested linguists is the development of techniques for identifying plagiarism in texts: that is, the unacknowledged use of another author's work. As well as obviously being a matter of concern in an academic context (Johnson, 1997), this issue is also of interest in literary contexts and as far as it relates to copyright law and trademark disputes.

Coulthard and Johnson (2007) identify several problems with the way plagiarism is defined in university guidelines, beginning with the focus on substantial verbatim borrowings when most cases involve some degree of editing of borrowed texts. Further to this, they claim, there has been a commitment to establishing intentionality in plagiarism cases, which is incredibly difficult to achieve. Thus, linguists often find themselves being asked by universities to contribute to discussions on how best to identify student plagiarism, and techniques for doing so have been based on the concept of idiolect—that is, the language of the individual. Although a certain degree of overlap is expected between the vocabularies of two authors writing on the same subject, we would nevertheless expect to find that not only will their choices differ from each other's, but that the *same* author writing on two separate occasions on the same topic will make different choices to express their meaning. As Coulthard and Johnson explain, "in any comparison of two texts, the more similar the set of items chosen, the greater the likelihood that one of the texts was derived, at least in part, from the other text" (Coulthard & Johnson, 2007, p. 187). Such insights have led to the development of software such as CopyCatch Gold (Woolls, 2003) to identify the level of lexical similarity between texts. For more discussion see the entry on PLAGIARISM.

Linguists have also been called upon to provide their input in disputes over commercial trademarks, acting as expert witnesses in cases where companies have claimed ownership not merely of a name, but of particular morphemes. Often the issue is the extent to which a trademarked term has slipped into general usage with a generic meaning. This issue is discussed in LINGUISTIC ANALYSIS OF DISPUTED MEANINGS: TRADEMARKS.

Forensic Phonetics

Naturally, linguistic evidence in criminal or civil cases can be spoken as well as written, and it is with the former type of evidence that forensic phoneticians concern themselves. Speaker identification—the question of whether two or more recordings of speech (from suspect and perpetrator) are from the same speaker—forms a significant proportion of their work and this can be achieved with the phonetician's ear alone, with speaker identification software, or a combination of the two.

Forensic phoneticians are also called upon to create sociolinguistic "profiles" of unknown speakers, drawing on their knowledge of regional and social variation to build up a picture of a speaker in order to narrow the search for suspects. This was the case in the famous

“Yorkshire Ripper” enquiry during the late 1970s in the United Kingdom (Ellis, 1994). A cassette recording of a man claiming to be the killer was sent to police investigating a series of murders of women in the north of England, and Ellis was able to ascertain that the speaker was from the Sunderland area in the northeast of the country. On the basis of further investigations he was able to narrow the speaker’s origin down to a small village on the north bank of the River Wear. Convinced the voice on the tape was that of the “Ripper,” the police relocated their search, against the advice of the linguists involved in the case. As it transpired, the police had misjudged the significance of details provided in the recording, and the speaker on the tape was a hoaxer. Peter Sutcliffe, who had spent his entire life in West Yorkshire, was convicted on 13 counts of murder in 1981. The hoaxer, who was responsible for the diversion of police resources to the wrong part of the country at a crucial stage of the investigation, remained undetected until 2005, when on the basis of new DNA evidence John Humble was identified as a suspect. The opinion of forensic phoneticians was sought again (French, Harrison, & Windsor Lewis, 2006), and preliminary investigations revealed a number of important similarities between the hoax tape and Humble’s voice.

Forensic phoneticians are also required at times to give their opinions on the use of voice line ups in criminal investigations and evaluate the competency of ear witnesses, assess the content of disputed utterances, and assess the authenticity of recordings (French, 1994).

Legal Language and Comprehensibility

As Coulthard and Johnson (2007) point out, “anyone who hears the term ‘*legal language*’ thinks immediately of grammatically complex, sparsely punctuated, over-lexicalized, opaque written text” (Coulthard & Johnson, 2007, p. 35). Explanations for this specialized code are to be found in both the history of common law (to this day legal English displays heavy influence from French), and in how the language needs to function (Tiersma, 1999). Certain legal tasks can only be accomplished with certain performative utterances, for example, and the need for precision, in both spoken and written legal language, is paramount (Gibbons, 2003). However, as many linguists working in the area have noted, this has frequently meant compromising on comprehensibility, rendering legal language “impenetrable . . . criticized for its obscure expressions and circumlocutions and tortuous syntax, apparently meaningless repetitions and archaisms” (Coulthard & Johnson, 2007, p. 37). While some have argued that the complexity of legal English is an intentional attempt to alienate and disadvantage the layperson, convincing them of the necessity for legal professionals in interpreting crucial texts, others have understood it as merely a by-product of legal drafters’ striving for ambiguity-free, precise language.

Gibbons (2003) sets out to identify the comprehension difficulties experienced by many speakers of English when faced with the legal register, and goes some way toward addressing these issues. He points out

the Common Law presumes that “ignorance of the law is no defence”. If the law is presented in language that cannot be understood by the people to whom it applies, this presumption can lead to grave injustice as well as logical absurdity. (Gibbons, 2003, p. 162)

Thus, the intelligibility of legal texts is of crucial importance if we want to ensure equality before the law. Unsurprisingly, then, law is a context around which the Plain Language movement have organized many of their campaigns, with some success (Gibbons, 2003).

One type of legal text that has roused significant interest from linguists in terms of its comprehensibility is judges' instructions to juries (Tiersma, 1999; Dumas, 2002; Heffer, 2006). As well as the complex syntax of the LANGUAGE OF JURY INSTRUCTIONS, particular specialist phrases such as "reasonable doubt" and "lesser included offence" have been singled out as potential problem sources. Dumas (2002) pays particular attention to the problems inherent in such phrases, focusing on a case which had resulted in the defendant receiving the death sentence, and in which she herself had later delivered an expert report on the comprehensibility of a set of jury instructions. Dumas notes that

there was a high likelihood that jurors understood some key terms in several different ways and that they understood some terms in ways different from those intended by the Court . . . the death sentence was imposed as a result of decisions made by jurors who had not understood their instructions. (Dumas, 2002, p. 247)

Spoken Legal Interaction

As forms of institutional talk, the interaction that occurs between police officers and suspects or witnesses in a police station, and between lawyers and witnesses or defendants in court, is inherently asymmetrical. That is to say, all participants do not have equal speaking rights, or equal access to the same interactional resources. Rather, the speaker who represents the institution—the police officer or the lawyer—controls the direction and structure of the interaction in order to address particular institutional goals. This, coupled with their increased knowledge about the relevant processes, puts institutional representatives in a position of advantage, thereby often disadvantaging lay participants. Many linguists have therefore drawn their data from these settings, in order to better understand how interactional control is exerted, how participants are disadvantaged, ways in which control can be resisted, how accounts are negotiated, and so forth. In some cases, particularly when the lay participants happen to be children, or vulnerable adults, researchers have studied these patterns in order to make recommendations for practitioners.

Heydon (2005) provides an overview of police interviewing in Australia grounded firmly in linguistic analysis, noting that, unsurprisingly, interviews with suspects are typically constructed of chains of question-and-answer adjacency pairs, with first pair parts being routinely allocated only to interviewers. This recurrent pattern, she observes, has the effect of maximizing interviewers' access to interactional resources while simultaneously restricting suspects' access to those resources. Suspects, unlike interviewers, are not able to produce first pair parts that introduce, maintain, or suppress topics—while interviewers have the power to initiate disjunctive changes of topic, suspects must rely on gradual step-wise transition and topic development confined to second pair parts. These issues of power and interactional control in suspect interviews are also explored in Haworth (2006) and Newbury and Johnson (2006), which both draw on data from police interviews with the prolific serial killer Dr. Harold Shipman to demonstrate ways in which interviewees can actively resist and challenge interviewers' powerful position and controlling interactional behavior.

Shifting the focus to police interviews with *witnesses*, Rock (2001) explores the process of producing a written witness statement as a result of several stretches of spoken interaction. She notes that some significant alterations are made to interviewees' original accounts, such as the removal of hedging and uncertainty, as well as a failure to investigate seeming contradictions. A statement is therefore the product of a series of negotiations between witness and statement taker, rather than a verbatim record of the witness' words as we might expect.

Within the context of the courtroom, where it has been noted that “it is difficult to imagine a context where verbal behaviour plays a more crucial role” (Harris, 1994, p. 156), linguists and discourse analysts have again tended to focus on the manifestation of institutional power and ideology (e.g., see Matoesian, 1993; Conley & O’Barr, 1998). The courtroom is a site where patriarchal and middle-class ideologies are expressed and enforced upon the laypeople involved, and there are several linguistic means by which this is achieved. In his study of the micro-linguistic processes at work during a rape trial, for example, Matoesian (1993) noted that rape victims are re-victimized by defense lawyers through these processes. Given the constraints on the types of turns witnesses are entitled to produce in this context, lawyers are able to make strategic use of silence to cast doubt on witnesses’ credibility; they are able to manipulate question form to further constrain witnesses’ responses; and they can be selective in reproducing elements of witnesses’ accounts in order to best support their client’s version of events. Though, as in police interviews, resistance on the part of the cross-examined witnesses is possible, it is generally short-lived. Thus, “the linguistic resources available to the lawyer are simply too many and those available to the witness too few” (Conley & O’Barr, 1998, p. 27).

The interviewing and cross-examining of children in criminal contexts has also been scrutinized from a linguistic perspective (Brennan, 1994; Aldridge & Wood, 1998; Aldridge, 2007). The use of closed questions, for example, has been shown to prove quite problematic for children, as have (to varying degrees) negatively formed utterances, nominalizations, multifaceted questions, specific and difficult vocabulary, quotations, repetition, and grammatical embedding (Brennan, 1994). Despite the research and resources that have gone in to training police officers in age-appropriate questioning techniques, and the positive impact this has had on children’s experiences of the police interview, the effects have yet to reach the courtroom. Problems identified by Aldridge (2007) center on question form and the dominant and repetitive style of cross-examination, “where the child is disempowered and the jury is led by the lawyer’s questioning” (Aldridge, 2007, p. 79). Aldridge goes on to make recommendations for judges to take a more controlling role over lawyers’ questioning style, in order to remove the child witness from this powerless position. These issues are discussed in the entries on FORENSIC DISCOURSE ANALYSIS, LANGUAGE OF COURTROOM INTERACTION, LANGUAGE OF POLICE INTERVIEWS, and LINGUISTIC DISADVANTAGE OF CHILDREN IN LEGAL CONTEXTS.

Cross-Cultural Issues and Legal Interpreting

The last 20 years have seen a growing interest from sociolinguists in addressing the difficulties encountered by speakers of varieties other than the official language when they come into contact with the legal process. The focus has been on topics as diverse as needs assessment for legal interpreting; the role of the interpreter in the communicative process; assessing national origins of asylum seekers; and the experiences of indigenous groups and other non-native speakers of the dominant language within the investigative and judicial settings.

Eades (1994), for example, focuses on miscommunication between Australian Aborigines and representatives of the Australian legal system, which arises out of a clash between the two groups’ verbal and nonverbal communicative norms. For example, while directly seeking information with interrogatives is a relative rarity in Aboriginal English, this is the unmarked choice for speakers of standard English. Furthermore, the legal process in Australia is based on question-and-answer sequences at every stage (Eades, 1994, p. 241). Questions provide lawyers and interviewing officers with a powerful resource for controlling talk in the courtroom and interview room, and all witnesses are therefore disadvantaged

to some extent in these types of interaction. However, for Aboriginal people the disadvantage is compounded by a number of specific differences between their own variety of English and that of the court. Communicative difficulties encountered by Aboriginal suspects have wide-reaching consequences for their experiences of the system, and have been identified as a potential contributory factor to their overrepresentation within the courts and prisons. Research such as Eades's has resulted in suggestions for developments in the ways that Aboriginal people are treated by the legal system.

Berk-Seligson (1999) discusses one particular effect of court interpreting on testimony—the interpreter's impact on the coerciveness of leading questions—in the context of US courts. Finding that a significant proportion of the leading questions drawn from her Spanish-English data were interpreted inaccurately in terms of their pragmatic force, she concludes that even fully certified interpreters make an overwhelming number of errors in this regard. While interpreters performed well in transmitting the *semantic* content, the intended coerciveness of lawyers' questioning was often lost. Thus, she claims, pragmatic equivalence is not achieved, and non-English or limited-English defendants lose their right to be "linguistically present" at their own trials. Her recommendations include a greater emphasis on pragmatic force and coerciveness within interpreter training programs and certification examining boards, thus minimizing the potentially damaging shift in pragmatic force that can be caused by inaccurate interpretation during the process of LEGAL INTERPRETING.

Professional Organizations

The International Association of Forensic Linguists (IAFL), www.iafl.org, consists of linguists working in all areas of language and law, and exists to promote the exchange of ideas between academic linguists and legal and investigative practitioners, as well as to alleviate language-based inequality in legal contexts. Developing the practice and ethics of linguists' expert testimony is a further goal of the association.

The International Association for Forensic Phonetics and Acoustics (IAFPA) www.iafpa.net, seeks to foster research and provide a forum for the interchange of ideas and information on practice, development, and research in forensic phonetics and acoustics, and set down and enforce standards of professional conduct and procedure for those involved in forensic phonetic and acoustic casework.

The International Journal of Speech, Language and the Law (IJSLL), www.equinoxjournals.com/ojs/index.php/IJSLL, is the official journal of both the IAFL and the IAFPA, and publishes peer-reviewed articles on all aspects of language and law on a biannual basis. The journal also carries reports on legal cases, PhD abstracts, conference reports, and book reviews.

Formal and Functional Approaches to Grammar

RICARDO MAIRAL USÓN

Introduction: The Initial Controversy

Over the past three decades the world of linguistics has been a witness to the controversy between formal and functional models of language. Formal approaches, which reduce linguistic analysis to a question of symbol manipulation thus focusing on compositional semantics, syntax and word classes (e.g., noun, verb), became dominant in linguistics with the advent of Noam Chomsky's transformational-generative grammar (TGG; Chomsky, 1965). In contrast, functional approaches, with Michael Halliday as one of its main exponents, were more concerned with the way people use language in context to communicate (see Halliday, 1978). Although, formal and functional approaches are commonly treated as opposed to each other, it must be borne in mind that they were formed independently. Chomsky's TGG, in fact, started as a reaction to behaviorism in linguistics, a tradition that can be traced back to Bloomfield's work, *Language* (1933), and his emphasis on dealing only with observable phenomena (among them stimulus-response behavioral patterns). Chomsky aggressively criticized behaviorism and developed a mentalistic and innatistic position about language and language learning. Halliday's systemic functional grammar (SFG), in its turn, has its origins in British linguist John R. Firth's emphasis on approaching linguistic analysis in terms of the different systems that are at work at a given level of description and in terms of the context-dependent nature of meaning.

Chomsky's Universal Grammar

Chomsky's influence peaked in the 1980s, with *Government and Binding Theory* and the emphasis on principles and parameters in the context of *Universal Grammar* (Chomsky, 1986). He started off from the assumption that children can learn the intricacies of their mother tongues in a surprisingly rapid and effective way on the basis of a deficient input of data. Such kind of learning suggests that all human beings are genetically endowed with an innate set of basic linguistics principles—a "Universal Grammar"—that guide them in their acquisition of complex human languages. Acquiring a native language is thus seen as a matter of parameterizing the universal principles that people are born with. Consequently, the linguist's task is not to describe linguistic output but rather to discover the mental makeup that underlies linguistic output, the so-called Internal language or I-language, as opposed to External language or E-language, which refers to the real output strings. In more recent times, Chomskyan linguistics has been inspired by the so-called Minimalist Program (Chomsky, 1995), which makes emphasis on the notions of economy of derivation and economy of representation. The new program features a derivational bottom-up approach to syntactic description, which replaces the top-down representations of X-bar syntax and makes use of two basic operations called merge and move. The first operation accounts for how syntactic objects are combined into new objects (e.g., "drink"

and “water” into “drink water”) and the second for movement of constituents within a syntactic representation.

The Rise of Alternative Formal Approaches to Generative Linguistics

The generative approach had an interesting side effect since it gave rise to a number of alternative approaches to grammar within the context of formal models; each model was the result of emphasis on different areas of syntax that had not been adequately dealt with by generative grammarians. Examples of such alternative models are David Perlmutter and Paul Postal’s relational grammar, which takes grammatical relations such as subject, object, predicate, and so forth, as primitives, Bresnan’s (1982) *lexical functional grammar* (LFG), which analyzes grammatical alternations as holding between lexical forms rather than through the application of rules at clause level (see also Bresnan, 2001), or Gazdar’s *generalized phrase structure grammar* (GPSG), which, in contrast to *generative grammar* (GG) is monostratal but uses phrase structure marking characterized by the inclusion of derived syntactic categories (see Gazdar, Klein, Pullum, & Sag, 1985).

The World of Functionalism

In parallel to the development of formal approaches to linguistics, other linguists turned their eyes to philosophers of language such as John L. Austin and John R. Searle (the fathers of *Speech Act Theory*; see Austin, 1962; Searle, 1969), Paul Grice (who accounted for implicit meaning on the basis of conversational maxims; Grice, 1975), and sociologists such as Emanuel Schegloff and Harvey Sacks, who were the originators of *Conversation Analysis* (see Sacks, Schegloff, & Jefferson, 1974). In this context, other linguists, such as Michael A. K. Halliday, Simon C. Dik, Talmy Givón, and Robert Van Valin decided to deal with the ability of social, contextual, and pragmatic factors to motivate grammatical phenomena (see, for example, Halliday, 1978; Foley & Van Valin, 1984; Givón, 1984, 1995, 2001; Dik, 1997a, 1997b; Halliday & Matthiessen, 2004; Van Valin, 2005; Hengeveld & Mackenzie, 2008).

Halliday’s approach, usually referred to as *systemic functional grammar* (SFG) laid emphasis on the idea that grammar is shaped by our experience of interaction in sociocultural contexts. Hence, SFG associates the notion of external explanation to social factors, that is, language is conceived as part of a social system of meaning or “social semiotics” (Halliday, 1978). In this approach, grammatical description was regarded as a matter of accounting for the ability of speakers to make choices from the intricate network of systems that give structure to language and map such choices simultaneously onto linguistic expressions in a meaningful way. Halliday’s grammar contemplated three broad dimensions of linguistic description that corresponded to the three great functions of language, that is, the ideational, interpersonal, and textual functions. The ideational function organizes our experience of the world and our way of reasoning on the basis of this experience. The interpersonal function deals with the speakers’ personal assessment of the contents of their messages and with their social function (the equivalent of speech act value in other theories). The textual function is about the way the message is structured in terms of informational prominence (thematization and topicalization) and of its cohesiveness. As for the way form is motivated by meaning in Halliday’s grammar, the actual configuration of a sentence (and of text) is the result of giving phonological shape to a combination of meaningful grammatical options. The approach is essentially paradigmatic, since the syntagmatic

properties of clausal constituents arise from the meaning potential each option has within a system. The interaction between transitivity and voice is a case in point. A clause can be effective (i.e., it has an object) or descriptive (i.e., it has no object). If it is effective, there is a choice between active and passive, which means that passive grammatical form (where the object becomes unmarked theme, thus serving an option from the textual system), with its syntagmatic properties depends on the way the transitivity system works paradigmatically.

Van Valin's *role and reference grammar* (RRG) and Dik's *functional grammar* (FG) argue that a functional approach to language needs to embed semantics and syntax within the "all-encompassing framework" of pragmatics. This view is expanded to include discourse in FG's successor, *Functional Discourse Grammar* or FDG (Hengeveld & Mackenzie, 2008), which sees the discourse "move," rather than the clause or the sentence, as the greatest unit of analysis. RRG, FG, and FDG place greater emphasis on syntagmatic issues but they are also sensitive to the paradigmatic properties of grammar (e.g., originally in FG predicates were organized into classes through stepwise lexical decomposition and terms and operators were classified into different contrasting sets). However, the descriptive elements have not been fully systematized in terms of networks as has been the case in SFG.

RRG and FG also postulate that linguistic theory needs to achieve three standards of adequacy, that is, psychological, pragmatic, and typological, besides the widely accepted standard of explanatory adequacy (i.e., the goal to account for the largest amount of phenomena through the least number of rules or principles), which was first postulated by Chomsky. According to the standard of psychological adequacy, grammatical explanation needs to be compatible with empirical findings in psychology about human processing and conceptualization (Dik, 1997a). The standard of pragmatic adequacy seeks to make the linguistic account sensitive to the role of language as a tool for communication. Finally, typological adequacy is attained when the linguistic account formulates generalizations that are valid across languages.

Both FG and RRG, although semantically and pragmatically motivated, feature a formal descriptive apparatus. For example, FG predicate frames are fully explicit semantic representations with feature specifications and their associated variables; predications, propositions, and illocutions are constructed on the basis of operators that have different predicates, terms, and other higher-level structures within their scope. Halliday's grammar, although it gives detailed descriptions of functionally motivated form, makes no use of a formal descriptive apparatus based on operators and variables, such as the one in FG. This characteristic of Dik's FG makes it fit nicely into the context of formal grammars, with two crucial differences: (a) in Dik's approach linguistic explanation makes use of pragmatic and discourse categories (especially in FDG); (b) grammar is semantically motivated and therefore formal categories should be interpreted within the larger framework of semantics and pragmatics.

Dik's FG is essentially a meaning construction model that gives rise to fully specified semantic representations at different levels of description (predicational, propositional, illocutionary), which thus become available for morphosyntactic realization. Form is the result of realizing meaning representations in such a way that form–meaning pairings are not arbitrary but motivated. However, the FG derivational system lacks a syntactic level of representation, as has been postulated in FDG and also in RRG.

RG postulates a syntactic level, which consists of a number of syntactic templates that associate with the resulting semantic logical structures. RRG, like Dik's FG, makes use of the layered approach to semantic representation, which consists of predicate specifications that have variables within their scope. However, syntactic specifications are not the result of a set of realization rules but rather of a direct one-to-one mapping from meaning to form and from form to meaning, where two macro-roles, actor and undergoer, play an

essential semantics–syntax linking role since they generalize across specific semantic argument types. One of the most outstanding contributions in RRG is the bidirectional linking system in that it maps both from syntax to semantics and from semantics to syntax. In this way it models aspects of what both the hearer and the speaker do in a communicative exchange. Most other theories, including FG, are unidirectional, in that they attempt to account only for what in RRG and FDG terms is the semantics-to-syntax linking. This way of dealing with syntax provides RRG with a robust formal apparatus that is at least as successful as the corresponding systems of purely formal model. But the RRG proposal has the advantage over formal models of being capable of dealing with the semantics–syntax interface and of endowing the model with a clear pragmatic and discourse dimension. For example, RRG makes use of focus assignment patterns, which, although different from the treatment by Dik and Halliday (see Butler, 2003), brings this approach into line with other functional approaches.

Toward a Possible Complementariness of Approaches

It is often taken for granted that the formal and functional approaches of language are mutually exclusive since the former are a case of I-linguistics while the latter are E-linguistics. However, as we have seen, this is not actually the case since formal models have increasingly focused on the efficiency of the system while functional models have made serious attempts to deal with the structural properties of language and to capture them through a formally explicit descriptive apparatus. Interestingly enough, Chomsky himself in *Rules and Representations* seemed to suggest that the two approaches are compatible when he claimed that the “study of performance and the study of competence are mutually supportive” (Chomsky, 1980, p. 226). Chomsky made the distinction between competence and performance as far back as 1965, as he was trying to determine the scope of linguistic theory. Competence, which was the object of linguistic theory, was defined as the perfect knowledge that an ideal speaker-hearer, living in a completely homogeneous speech community, has of his language. Actual performance, in contrast, was characterized as being affected by “such grammatically irrelevant conditions as memory limitations, distractions, shifts of attention and interest, and errors (random or characteristic)” (Chomsky, 1965, p. 3). However, later on Chomsky became aware that performance included pragmatic principles such as those postulated by philosophers of language and processing constraints—such as construal phenomena largely explored by cognitive scientists concerned with language—which actually gave shape in systematic ways to the speaker’s output. While functional linguists and later on cognitive linguists, such as Lakoff (1987) and Langacker (1987), argued that such principles and constraints had a direct impact on morphology and syntax, Chomsky still believed that syntax could be described with independence of external factors. However, he decided to refine the competence/performance distinction (which he has never discarded) and proposed the division of labor between E-linguistics, which focuses on speakers’ performance (understood in a broad sense), and I-linguistics, which focuses on speakers’ competence (understood in the restricted sense of syntax and syntactically relevant elements from outside syntax proper). Chomskyan linguistics thus became I-linguistics, while functional and cognitive-linguistics approaches, which postulated the semantic, pragmatic, and discourse motivation of syntactic phenomena, were a matter of the E-linguistics perspective.

Functional linguistics has generally taken a negative stand on the Chomskyan approach, which has usually been judged as depriving linguistic explanation of its true character since linguistic form is generally motivated by its function and can thus be better understood with reference to the latter (see Dik, 1986). However, there are structural relationships

in language which can be stated with independence of possible functional motivations. One such relationship is captured by the notion of government. A governor has to be a node that does not dominate the governee while the nodes that dominate the governor are maximal projections and dominate the governee. The structural notion of government is useful to account for the generalization that a *that*-complementizer cannot be immediately followed by a trace resulting from movement. Consider the following sentence,

- (1) Whom_i did you say [t_i that [he saw t_i]]?

In (1) the movement of “whom” to the sentence initial position has left a trace, t_i, which is governed by the verb “saw.” However, note the ungrammaticality of

- (2) *Who_i did you say [t_i that [t_i saw John]]?

In (2) the *that*-complementizer is followed by a trace, which makes the sentence ungrammatical. The structural principle that makes use of this government relationship is known in the generative linguistics literature with the name of Empty Category Principle. This principle, in fact, is but a way of accounting for the fact that it is generally more difficult to move up a *wh*-word from a subject position than from an object position. The issue is more complex, but even this partial description is enough to make us appreciate the value of purely structural relationships in linguistic description and explanation.

However, whatever the value of some formal explanations, on many occasions, a functional account may cast greater light on grammatical processes than a purely formal perspective. By way of illustration, we may consider the problem of the broad and narrow scope of *whether*-complementizers as described in Hoekstra and Kooij (1988) and the more functionally oriented motivational explanation provided by Radden and Panther (2004, pp. 11–13). Consider:

- (3) Where did John say that we had to get off the bus?
 “John said where that we had to get off the bus?”
 “John said that we had to get off the bus where?”
 (4) Where did John ask whether we had to get off the bus?
 “John asked where whether we had to get off the bus?”
 “*John asked whether we had to get off the bus where?”

Example (3) is either a question about the place where John said something, that is, that the protagonists have to get off the bus (which is a case of wide scope of *where*), or about where the protagonists should get off the bus (which is a case of narrow scope of *where*). However, in example (4) only the wide scope reading is possible, that is, a question about where John asked a question. Obviously, *that*-clauses allow extraction of elements while *whether* is a barrier to this process. The problem with this description is that it does not account for why we have such a barrier. But we can find motivations for this barrier outside syntax. Radden and Panther observe that *say* is one of the most neutral, non-salient verbs of communication. In (3) the information that is more relevant or foregrounded is the location to get off the bus; in (4), in contrast, which makes use of a more specific speech act verb, the addressee’s attention is drawn to the communicative act itself, which favors the wide scope interpretation.

Often functional explanations are useful to account for other linguistic phenomena for which a purely formal account is impossible. For example, think of the phenomenon known as *enriched composition* (Jackendoff, 1997). As Jackendoff observes, there are verbs like *enjoy* and *begin* in English that canonically subcategorize a non-finite verb as their governed

complement: *He enjoyed/began dancing the Polka/drinking pale lager*. But it is also possible to find these verbs with a nominal complement: *He enjoyed/began the Polka/the pale lager*. The problem in these cases is that the kind of action carried out by the protagonist (the clausal subject) is implicit and has to be determined on the basis of the context. Evidently, it is not possible to compose the meaning of verbs like *enjoy* and *begin* and their nominal complements on the basis of syntactic relations. Jackendoff (1997, p. 61), whose work straddles the boundaries between formal and cognitive-functional linguistics, proposes a solution based on expanding the meaning of the complement by looking into its world knowledge structure. Interestingly enough, this solution amounts to recognizing that the complementation pattern of *enjoy* and *begin* is motivated by factors that are external to syntax, which is the way problems of this nature are accounted for in functional and cognitive approaches to language. Ruiz de Mendoza Ibáñez and Pérez Hernández (2001) use external criteria and argue that a high-level metonymy, *object for action*, is responsible for licensing this phenomenon.

The concept of motivation has thus become central to functional linguistics (see Givón, 1995, p. 16; Butler, 2003, p. 51), but it is not exclusive of this orientation (González & Butler, 2006, pp. 49–50). In fact the search for motivation is also central to cognitive linguistics, as explicitly claimed in the earliest work of the founding fathers of this movement (e.g., Lakoff, 1987; Langacker, 1987). The difference is that functionalists seek motivation in the social or communicative, or both social and communicative, aspects of language use, whereas cognitive linguists tend to look for motivation in the way we perceive and interpret experience. But, ultimately, since the social aspects of language are based on cultural convention, which is often grounded in the way people interpret experience, the cognitive linguists' understanding of motivation overlaps with the functionalists' use of this notion and provides a clear point of contrast with formal approaches where meaning is seen as merely interpretive.

Formal Models of Bilingual Speech Production

DAAN HERMANS

Overview

How do bilinguals manage to produce words in the language in which they intend to speak? This is a puzzling question that has occupied many researchers working in the field of bilingual word production. Since the early 1990s, analyses of slips of the tongue and experimental studies have revealed that both a bilingual's languages are activated when bilinguals produce words in one language. The observation of cross-language activation has raised the question of how bilinguals exert control over their bilingual speech production system. This seems to be especially vital for unbalanced bilinguals who intend to speak in their less dominant language. Two different types of proposals have been put forward in the literature. This entry describes the available evidence on cross-language activation and presents two views on how bilinguals exert control on their bilingual speech production system. Finally, there is a discussion of one study on monolinguals, unimodal bilinguals (e.g., English–Italian bilinguals) and bimodal bilinguals (e.g., American Sign Language–English bilinguals) that demonstrates how studying different groups of bilinguals may provide a unique opportunity to reveal the fundamental characteristics of word production in bilinguals.

Cross-Language Activation in Word Production

To date, the most compelling experimental demonstration of cross-language activation that extends all the way to the level of phonology in language production has been reported by Colomé (2001). Colomé conducted a series of phoneme-monitoring tasks with Catalan–Spanish bilinguals. Participants were asked to decide whether or not a particular phoneme was part of the Catalan name of the picture. The phoneme was either part of the Catalan name of the picture (/t/ in *taula* 'table'), part of the Spanish name of the picture (/m/ in *mesa* 'table'), or not part of either the Catalan or Spanish names of the picture (/f/). The rationale was that if the Spanish name of the picture were phonologically co-activated during the phoneme monitoring task in Catalan, participants should take more time to correctly reject a phoneme that was part of the Spanish name of the picture than an unrelated phoneme. In a series of experiments, this prediction was confirmed (see, for similar results using the picture–picture paradigm, Colomé & Miozzo, 2010).

Another quite convincing demonstration of cross-language activation has been found in studies in which the naming latencies for pictures with cognate or non-cognate names were compared (Costa, Caramazza, & Sebastián-Gallés, 2000; Hoshino & Kroll, 2008). Cognates are translation equivalents with similar orthography, phonology, or both, like the English and Spanish words *lamp* and *lámpara*. Non-cognates are translation equivalents with a different orthography, phonology, or both, like the English and Spanish words *table* and *mesa*. Costa et al. instructed Catalan–Spanish bilinguals and Spanish monolinguals to

name pictures with non-cognate and cognate names. The rationale was that if the names of the pictures in both languages were phonologically co-activated, bilinguals, but not monolinguals, should name pictures with cognate names faster than pictures with non-cognate names. Again, the results confirmed this prediction. A subsequent study by Hoshino and Kroll (2008) demonstrated that cross-language interactions persist even when the two languages are distinct in their written form, as in the case of Japanese–English bilinguals. The results described above suggest that the parallel activity of similar phonology across the two language alternatives creates convergence that facilitates processing, and suggest that cross-language activation is a natural part of language production in bilinguals.

Recently, studies on bilingual word production have started to investigate the scope of cross-language activation (e.g., Jared & Kroll, 2001; Hermans, Ormel, van Besselaar & van Hell, in press). These studies have drawn upon Grosjean's notion of the bilingual continuum. Grosjean (1998) has argued that the extent to which a bilingual's languages are activated during language production depends upon a variety of factors such as (a) the proficiency of bilinguals in both languages, (b) their knowledge and expectations of the language proficiency and language preference of the interlocutor(s), and (c) the knowledge of their language communities on code switching and language mixing.

In line with this proposal, Kroll, Bobb, and Wodniecka (2006) conducted an extensive review of the experimental evidence obtained in the previous two decades, and concluded that the bilingual language production system is a dynamic system that can operate in different language activation states, depending on, for instance, task demands and the composition of the stimulus list. Hermans et al. (in press) obtained evidence in support of the proposals mentioned above. Hermans et al. found that cross-language effects in a phoneme monitoring task in the second language (L2) were affected by the proportion of filler pictures with cognate names in unbalanced first language (L1) Dutch–L2 English bilinguals. Cross-language activation effects were observed when (a proportion of or all) filler pictures had cognates names in Dutch and English, but not when the filler pictures consisted of exclusively pictures with non-cognate names. In other words, although the scope of cross-language activation has yet to be determined, the results from experimental studies conducted so far have revealed cross-language activation during language production.

More evidence for cross-language activation was obtained in an extensive study by Poulish (1999) on speech errors in natural L2 speech production of L1 Dutch speakers with different levels of proficiency in L2 English. Poulish found that about 30% of the errors unbalanced bilinguals produced during L2 speech production carried traces of the L1. More than one-fifth of the errors were lexical substitutions, in which speakers produced an L1 word instead of the intended L2 word (e.g., *yes, she heeft (has) uh she has uh, big ears*). Interestingly, the number of cross-language lexical substitutions sharply decreased as the level of L2 proficiency of bilinguals increased. To illustrate, third-year high school students produced more L1 lexical substitutions during L2 speech production than did second-year university students. This finding suggests that the control bilinguals can exert over their speech production system grows as their L2 proficiency increases (Abutalebi & Green, 2007). Interestingly, Poulish (1999) also observed a few so-called code blends (e.g., *two form which bow towards elchother*, a blend of L2 English *each other* and its L1 Dutch translation equivalent *elkaar*). The observation of crosslingual blends is consistent with the experimental evidence on cross-language phonological co-activation described earlier.

In evaluating how informative slips of the tongue are for monolingual and bilingual speech production models, it is often argued that such slips may result from an occasional derailment of the language production system. In this scenario, slips of the tongue do not reflect the "normal" process of lexical access in bilinguals. However, one should be very cautious in dismissing evidence from studies analyzing slips of the tongue in natural language production. Work on language production in bilinguals constitutes a relatively

new scientific field. As a consequence, work on developing and falsifying theories of word production in bilinguals has gone hand in hand with the search for appropriate experimental paradigms. To illustrate, the usefulness of two paradigms that have been used most frequently in bilingual word production research, namely the picture–word interference task (Hermans, Bongaerts, De Bot, and Schreuder, 1998; Costa, Miozzo, & Caramazza, 1999) and the language-switching task (Meuter & Allport, 1999), has recently been challenged (Finkbeiner, Almeida, Janssen, & Caramazza, 2006; Kroll, Bobb, Misra, & Guo, 2008; Colomé & Miozzo, 2010; Hermans et al., in press). The results obtained from studies in which one of these paradigms were used will therefore be excluded from this review.

Theories of Word Production in Bilinguals

Bilingual models of word production have drawn heavily upon the Levelt’s (1989) theory of language production in monolinguals. Central within this theory is the process of lexical access, during which conceptual representations are mapped onto lexical representations. Lexical access comprises two steps: lemma selection and phonological encoding. Lemma selection is often viewed as a competition process in which lexical items which match or partly match the conceptual specifications are activated, and compete for selection (but see Finkbeiner, Gollan, & Caramazza, 2006; Mahon, Costa, Peterson, Vargas, & Caramazza, 2007). Within this framework of language production, models of bilingual word production started to emerge in the last decade of the 20th century.

Central within all models is the notion that the language in which a speaker intends to speak must be specified at the conceptual level. De Bot and Schreuder (1993) have pointed out that information regarding the language in which a speaker intends to express his or her thoughts, the so-called language cue, must be specified in the conceptual message, as languages differ on how combinations of conceptual primitives are expressed by combinations of lexical items.

In the models proposed by Costa et al. (1999) and LaHeij (2005) this language cue guarantees the selection of words in the appropriate language (see Figure 1). These models assume that the intention to speak in a language will either increase the activation level

Figure 1 Models of “easy lexical access” in bilinguals: Costa et al.’s (1999) on left; LaHeij’s (2005) on right

(or lower the selection threshold) of lexical candidates in the target language (LaHeij, 2005; Finkbeiner et al., 2006) or inform the lexical selection mechanism to consider only lexical representations for selection that belong to the language selected for production (Costa et al., 1999).

Although they are different in their assumptions on how language information is used to select words from the language selected for production (see for a review Finkbeiner et al., 2006), these models assume that the selection of words in the appropriate language is guaranteed naturally and quite automatically by the intention to speak in that language. One of the appealing advantages of these models of “easy lexical access” in bilinguals is that they require the postulation of just one simple mechanism to explain how bilinguals are usually able to produce words in the appropriate language.

In contrast, the inhibitory control (IC) model proposed by Green (1998) assumes that the intention to speak in a language itself is not sufficient to guarantee the selection of lexical candidates in the language selected for production (see Figure 2). In Green’s model, language control is achieved through the implementation of so-called competing “task schemas” that in more general terms guide an individual’s behavior by specifying the goal of that individual in situations that allow multiple possible actions. However, the selection of a particular task schema (“speak in the L2”) itself is not sufficient in controlling activation in the language required for production (e.g., Kroll et al., 2008). Green’s model assumes that lexical representations for the language not selected for production are activated and compete for selection. These lexical representations need to be reactively suppressed, especially when unbalanced bilinguals intend to speak in their weaker language. As pointed out by Finkbeiner et al. (2006), Green’s IC model has built upon Levelt’s (1989) speech production model in its assumption that selection through competition characterizes lexical access in bilinguals. This assumption has recently been challenged in the monolingual domain (Mahon et al., 2007, but see for an alternative selection-through-competition account Abdel Rahman & Melinger, 2009).

Both types of models can explain most of the experimental results obtained in phoneme monitoring tasks, picture naming tasks, and picture–word interference tasks (see for a review Finkbeiner et al., 2006). In part, this is due to the different conceptions of these experimental paradigms that have allowed alternative explanations for the same experimental findings. Recently, researchers have turned to different experimental paradigms

Figure 2 Green’s (1998) inhibitory control (IC) model

to investigate whether or not the postulation of an additional mechanism, like a reactive inhibition mechanism, is necessary to explain how bilinguals are able to control their languages.

Do Bilinguals Need Inhibition to Exert Control Over Their Bilingual Production System?

Kroll et al. (2008) reviewed recent behavioral, effective refractory period (ERP), and neuroimaging studies. The authors concluded that although the available evidence is far from conclusive, it suggests that a bilingual's two languages are activated in parallel, and compete for selection. Kroll et al. argued that the postulation of an IC mechanism seems to be consistent with a wide variety of findings observed in behavioral studies (Christoffels, Firk, & Schiller, 2007; Wodniecka, Bobb, Kroll, & Green, *in press*) and in ERP and neuroimaging studies (Rodriguez-Fornells et al., 2005; Rodriguez-Fornells, De Diego Balaguer, & Munte, 2006; Abutalebi, & Green, 2007; Christoffels et al., 2007).

Christoffels et al. (2007) observed a language dominance reversal effect in their study on word production in Dutch–German bilinguals. This effect refers to the finding that, whereas picture naming in the L1 is usually faster than picture naming in the L2, this advantage disappears or is even reversed in experiments in which participants have to name pictures in a mixed language setting. Thus, Christoffels et al. observed a large mixing cost for the L1, but not for the weaker L2 (in the behavioral measures). This finding demonstrates that there is a mechanism that enables bilingual speakers to inhibit lexical representations in this (artificial) language mixing setting. However, it does not necessarily imply that such a (rather proactive) inhibitory mechanism is actually used in language production.

More direct evidence for IC in language production was obtained by Wodniecka et al. (*in press*, cited in Kroll et al., 2008). Wodniecka et al. used a competitor priming paradigm which involves a study and a test phase. Some of the pictures in the study phase were named in the same language in the study and the test phase (congruent condition), some of the pictures were named in different languages in the study and the test phase (incongruent condition), and some pictures in the test phase were not presented in the test phase (new condition). Wodniecka et al. argued that if bilingual word production is not characterized by competition and suppression, then naming a picture in a test phase should not be affected by the language in which the picture was named at the study phase. In other words, pictures in the congruent and incongruent conditions should be named faster than pictures in the “new” condition (attributable to repetition priming of the picture, its concept, or both). However, the results contradicted this prediction: Facilitatory effects were only observed for pictures that were named in the same language in the study and the test phase. Wodniecka et al. concluded that the absence of a facilitatory effect in the incongruent condition reflects an inhibitory component that counteracts the facilitation.

Results from neuroimaging studies also support the notion of an IC mechanism (Rodriguez-Fornells et al., 2005, 2006; Abutalebi & Green, 2007; Christoffels et al., 2007). To illustrate, Rodriguez et al. (2006) argued that language production in bilinguals requires cognitive control executed by the dorsal-lateral prefrontal cortex (DLPFC), an area that has been strongly associated with executive function. Rodriguez et al. proposed that the DLPFC mediates cognitive control in bilingual speech production through the interplay between a top-down selection-suppression mechanism and a local inhibitory mechanism.

Finally, in several studies bilingualism has been found to be associated with cognitive advantages (for a review see Bialystok, 2005). Bialystok and colleagues have argued that the requirement to resolve cross-language competition leads to cognitive benefits for bilinguals in the domain of executive function. In other words, the cognitive advantages found

in bilinguals are assumed to reflect an enhanced ability to ignore irrelevant information and to reduce conflict among competing alternatives. Note that this explanation of the cognitive advantages found in bilinguals fits well with Green's IC model. Although the cognitive advantages of bilinguals may also be explained by alternative models of bilingual word production, it has not been sufficiently addressed by these models.

Interim Summary

Studies on bilingual language production have revealed that both a bilingual's languages are activated when bilinguals produce words in one language. The evidence described in the previous sections is consistent with the view that words from both a bilingual's languages compete for selection, and that IC is necessary to prevent bilinguals from producing words in the language not selected for production (Kroll et al., 2008). However, it is important to note that, at present, there is no direct evidence available which demonstrates either within-language or cross-language competition during language production in bilinguals (Finkbeiner et al., 2006, Abutalebi & Green, 2007). One of the challenges in the field of bilingual word production is to seek new experimental paradigms that can address this question more effectively.

Bimodal Bilingualism

One exciting possibility is that language production studies on unimodal and bimodal bilinguals may reveal some of the answers to the questions that need to be readdressed (Kroll & Hermans, in press). Bimodal bilinguals have one language that is signed and another that is written or spoken. For instance, children of deaf adults (CODAs) typically acquire both a sign language and a spoken language from birth. Emmorey and colleagues have argued that the language production system of bimodal bilinguals is fundamentally different from the language production system of unimodal bilinguals (Emmorey, Borinstein, Thomspson, & Gollan, 2008; Casey & Emmorey, 2009). For unimodal bilinguals, the articulatory systems are the same for both languages (vocal channel), and constrain how bilinguals deal with parallel activation of lexical representations in both languages during language production. Unimodal bilinguals can only speak in one language at a time, and must exert control on their language production system to avoid confusion by their interlocutors.

For bimodal bilinguals, the articulatory systems involved in the production of sign language (manual channel) and spoken language (vocal channel) are different. This allows them (to some extent) to produce words and signs simultaneously. A study by Emmorey, Borinstein, et al. (2008) revealed that even in the absence of an interlocutor (retelling a cartoon), bimodal bilinguals often produce code blends in natural language production.

Emmorey, Luk, Pyers, and Bialystok (2008) hypothesized that if the observed benefits to executive control for unimodal bilinguals can be ascribed to negotiating cross-language competition during language production, then only unimodal bilinguals, but not bimodal bilinguals, should reveal the executive function advantage. Emmorey, Luk, et al. (2008) administered a flanker task to unimodal bilinguals, bimodal bilinguals, and monolingual control participants. They found that monolinguals and bimodal bilinguals responded more slowly than unimodal bilinguals. No differences were found between the bimodal bilinguals and the monolinguals. The researchers concluded that the source of the bilingual advantage in executive function is localized at the level of choosing between competing alternatives along the same speech channel. It seems difficult to account for the findings observed by Emmorey, Luk, et al. (2008) without assuming that word production in unimodal bilinguals is characterized by competition that is resolved through a reactive IC

mechanism. This is the first piece of research to demonstrate how studies that include bimodal bilinguals can provide insights into the fundamental characters of bilingual word production.

Summary

How do bilinguals manage to produce words in the language in which they intend to speak? The answer may be straightforward and may be very appealing in its simplicity: The intention to speak in a language guarantees the selection of a word in the appropriate language. But alternatively, bilinguals may have to deal with cross-language competition by suppressing lexical candidates every time they produce a word. At present, there is no conclusive answer on how bilinguals exert control over their speech production system, even though several findings in the literature support the notion that the intention to speak in a language is not sufficient to exert control over one's bilingual language production system. At this point, the development of new experimental paradigms seems to be an absolute necessity to address this question in more depth. Nevertheless, the research findings obtained so far seem to support a statement Grosjean made over two decades ago: "Neurolinguists, beware! The bilingual is not two monolinguals" (Grosjean, 1989).

Formal Models of Bilingual Lexicons

NATASHA TOKOWICZ AND ALBA TUNINETTI

A number of models have been developed to describe the representation and processing of words in a bilingual's two languages. These models vary in the extent to which they make predictions regarding the development of proficiency versus describe a discrete stage of proficiency, in the extent to which their predictions are supported by formal mathematical formulas versus verbal descriptions, and, among the mathematical models, whether they propose that information is stored in localist representations (i.e., each item that is represented is stored in a single unit) versus distributed representations (i.e., each item that is represented is stored as the pattern of activation across a set of units). See Thomas and van Heuven (2005) for further discussion of the differences between these types of models in the bilingual domain.

Memory Representation Models

Some models of the bilingual lexicon are descriptive models that emphasize the way that word forms and meanings are represented in memory, and how words in the two languages and their meanings are interconnected. These models vary in terms of whether they propose that words from the two languages have direct access to meaning or not, and whether the relative strength of the connections varies among the representations.

One well-known memory representation model of the bilingual lexicon is the revised hierarchical model proposed by Kroll and Stewart (1994). This model is a descriptive model that was proposed to explain how first and second language words and their meanings are stored in memory, how they are interconnected, and how these interconnections change as a function of second language proficiency. The interconnections in the model vary in terms of their relative strength and direction. The revised hierarchical model is considered hierarchical because it hypothesizes that words and their meanings are stored at separate levels of representation. It further proposes that words in the two languages are stored separately from each other (i.e., in different memory stores), but that they access a shared meaning store. Lastly, the revised hierarchical model proposes that the interconnections among these representational stores are asymmetric, with first language words having stronger connections to their meanings than second language words. The connection from second language words to their translation equivalents in the first language is stronger than the reverse; this asymmetry reflects the over-reliance on first language mediation in the initial stages of some types of second language learning.

As a result of the asymmetric connections in the model, initially, translation from the first language to the second is proposed to involve access to meaning. This is because first language words are strongly connected to meaning, and will rapidly and automatically activate them. Furthermore, translation from the first language to the second will be slow and relatively error-prone because it requires that a second language word be activated via the relatively weak connection between meaning and a second language word. The revised hierarchical model also makes the prediction that with increased second language proficiency, the connection between second language words and their meanings will become

stronger. As a result, translation from the first language to the second will become increasingly fast and decreasingly error-prone. On the other hand, translation from the second language to the first is always predicted to rely on the strong connection from second language words to their first language translations. Thus, it is predicted that translation in this direction typically will not involve activation of meaning and therefore will be faster and less prone to error. Translation from the second language to the first is also predicted to be less influenced by meaning-related factors such as whether words are processed in semantically organized versus randomly ordered lists (Kroll & Stewart, 1994; see also Kroll, van Hell, Tokowicz, & Green, 2010). With increased proficiency, translation from the second language to the first is hypothesized to remain relatively more stable than translation from the first language to the second; therefore the two directions of translation become more similar and there is a decrease in the translation time and accuracy asymmetries.

The revised hierarchical model incorporates aspects of two previous descriptive models, the word association and concept mediation models of Potter, So, von Eckardt, and Feldman (1984). These models did not make predictions about changes in representation with increased second language proficiency. According to the word association model, second language words are directly connected to their translation equivalents, and they are connected to meaning only through these translation equivalents. Therefore, this model predicts that translation in both directions should occur solely via word-to-word connections. By contrast, the concept mediation model proposes that both first and second language words have equal access to meaning and therefore translation in both directions should be conceptually mediated. The revised hierarchical model expanded on these models by making predictions regarding changes that occur as a result of increased proficiency in the second language.

Two additional memory representation models that describe how words in the bilingual's two languages are interconnected are the distributed feature model (e.g., de Groot, 1992) and the distributed representation model (e.g., van Hell & de Groot, 1998). These two models are descriptive in nature and were not developed to account for changes as a function of increased second language proficiency. These models propose that first and second language words have equivalent access to meaning. The distributed feature model is similar to the revised hierarchical model in that it posits that first and second language words are stored separately but that they access the same meaning representations. Importantly, it also proposes that meanings are stored as sets of distributed features, and translation "equivalents" are likely to vary in their meaning overlap across languages. In particular, the model posits that concrete words, which refer to perceptible entities, are more likely to share features across languages than abstract words, which refer to imperceptible entities. Similarly, cognate translations, which share both meaning and lexical form, are proposed to share more aspects of meaning across languages than noncognate translations, which share meaning but not lexical form. The distributed representation model is an adaptation of the distributed feature model that represents both lexical form and meaning as distributed features, so it describes meaning and form similarity in a continuous fashion. These features allow the model to account for differential effects for cognates and for interlingual homographs, which share lexical form but are not translation equivalents.

The revised hierarchical model and distributed representation model have been combined into a single model called the distributed lexical/conceptual feature model (Kroll & de Groot, 1997) that applies the asymmetric connections of the revised hierarchical model to the distributed framework of the distributed representation model. This more recent model captures graded overlap at the lexical form and meaning levels while making predictions regarding changes that come with the development of second language proficiency.

Word Recognition Models

Some models of the bilingual lexicon are focused on the process of (visual or auditory) word recognition. These models make assumptions regarding the representations of words in the two languages and whether words from the language not currently in use compete for activation during the recognition process. These models are aimed primarily at describing the stable state of proficient performance, but also can simulate some aspects of less-proficient performance. Some of these models have been implemented mathematically, as described below.

The bilingual interactive model (BIA), posited by van Heuven, Dijkstra, and Grainger (1998), is an extension of the interactive activation model put forth by McClelland and Rumelhart (1981). The interactive activation models were used to simulate word recognition within a monolingual language system. The BIA model extended this framework to describe bilingual word recognition. Like the interactive activation model, the BIA model is limited to processing the orthographic features of visually presented words.

The BIA model is mathematically implemented and therefore can be used to simulate performance. The model consists of four layers of nodes, at the feature, letter, word, and language node levels. The nodes take letter representations from printed words as their visual input. Each letter activates words in either language that have the same letter in the same position, and inhibits words that do not overlap with the visual input in terms of the letter-to-location correspondence (Thomas & van Heuven, 2005). Interaction in the model arises from lateral inhibition, which occurs when an active node at a given level of representation reduces the activation of other nodes at that same level of representation. In other words, the more evidence that supports, for example, the presence of the word "cat," the more inhibition there will be of words that are not "cat." Additionally, the BIA model operates under the assumption of an integrated lexicon and nonselective language access, which assumes that both languages are activated during processing of either one (Thomas & van Heuven, 2005).

An important aspect of the BIA model is the addition of language nodes to the original interactive activation model. Because words are connected to the node of the language to which they belong, the model contains a basis for making a language decision (i.e., to what language does this word belong?) and can raise the activation of one language while inhibiting the other. This latter mechanism allows the model to account for differences in performance across experiments because the language nodes can serve as a type of language filter. Furthermore, the model is able to simulate data suggestive of selective access under some patterns of language node activation. The BIA model can also illustrate the effects of relative second language proficiency by adjusting the resting levels of activation of words, the method also used to simulate word frequency effects in the model.

To address the absence of phonological and semantic representations in the BIA model, Dijkstra and van Heuven (2002) proposed the BIA+ model, which is a descriptive model. Like the BIA model, the BIA+ model also has an integrated lexicon across languages and assumes nonselectivity. Whereas the BIA model used strong top-down inhibition from the language nodes to account for different patterns of findings in various tasks and stimulus contexts, the BIA+ model replaces this with a task/decision component that is affected by extraneous (extra-linguistic) factors and has the same effect on the model results. These models have progressed far in helping to explain bilingual word recognition during varied tasks, but future research is still needed to describe the effect of perceptual processing and context on bilingual word recognition more explicitly.

One effort to incorporate semantics in this framework is the semantic, orthographic, and phonological interactive activation (SOPhIA) model (van Heuven & Dijkstra, 2001), which

is a mathematically implemented version of the BIA+ model. This model is undergoing further development with the goal of describing additional bilingual word recognition phenomena.

A related model of word recognition is the bilingual interactive model of lexical access (BIMOLA) proposed by Grosjean (1988) to account for spoken word recognition. Like the BIA and BIA+ models, BIMOLA was inspired by an interactive activation model, specifically the TRACE model of speech perception (McClelland & Elman, 1986). Unlike the BIA and BIA+ models, BIMOLA assumes selective access of words in the first and second language, such that the only competitors for activation are within-language competitors.

Memory Representation Versus Word Recognition Models

Recently, a debate has emerged regarding the relative merits of the memory representation versus word recognition models. Specifically, some researchers feel that memory representation models such as the revised hierarchical model should be left behind in favor of more recent word recognition models such as the BIA and BIA+ models (Brysbaert & Duyck, 2010; Brysbaert, Verreyt, & Duyck, 2010). This position has been challenged by other researchers who acknowledge the specific contributions of all models because they allow researchers to articulate ideas more clearly and to advance understanding (Kroll et al., 2010). Having a variety of types of models may be especially important to consider in light of the dimensions along which the memory representation and word recognition models vary, as described here.

Self-Organizing Map Models

Some models of the bilingual lexicon seek to explain how it is possible for a bilingual to maintain separation between their two languages. In particular, self-organizing map models (Kohonen, 2001) have been used as a method for understanding how representations are organized. These models are mathematical (connectionist) models that use particular trained sequences. Several versions of this kind of model have been developed to explain various facets of the bilingual lexicon. The DevLex-II model (Li, Zhao, & MacWhinney, 2007) has an input lexicon made up of phonological features, a semantic map that includes semantic features based on co-occurrence metrics, word associations, and other information as presented in a thesaurus, and an output lexicon made up of phonological output features. This model has recently been extended by Zhao and Li (2010) to describe how the time at which a second language is learned relative to the first language impacts second language vocabulary development and use. This version of the DevLex-II model was trained on words in three orders: (a) the two languages presented simultaneously, simulating simultaneous bilingualism; (b) the first language presented first with second language words presented shortly thereafter, simulating early learning; and (c) the first language words presented first with second language words presented much later, simulating late learning. The model proposes that when words from the two languages are learned simultaneously, the words organize into separate representational spaces and the semantic and phonological representations for the first and second language are the most distinct. When the second language is learned early, these representations are still quite distinct, but when the second language is learned late, the representations are the most similar, indicating that the second language is parasitic on the first.

Word Production Models

The models described above all focus on representation or comprehension. Relatively fewer models have focused on the details of bilingual language production. The models that do focus on bilingual production are descriptive models that describe a discrete point in second language proficiency. These models make predictions regarding the degree to which candidates in the two languages are considered during the speech production process.

Speech production in monolinguals and bilinguals is thought to progress from the conceptualization of the message, at which point an idea is generated. Then, appropriate lexical candidates are identified. These are words that could be used to convey the intended message, and words that are related to those words. Finally, the phonology that is used to express the selected word is activated.

Monolingual and bilingual production differ in terms of the stage at which lexical candidates are identified. Models of bilingual production generally agree that candidate lexical items are considered from both of a bilingual's languages. These candidates are activated because they are related to the intended message in terms of meaning, even if they are not in the intended language. At present, bilingual production models differ in the extent to which they predict that the selection mechanism itself is language selective or nonselective in nature (i.e., whether words from one versus both languages are considered for output).

Production models with a language-specific selection mechanism (e.g., Costa & Caramazza, 1999) assume that the production system is insensitive to the activation of words from the nontarget (unintended) language and therefore words from the correct language will typically be selected. Thus, words from the nontarget language become activated but are not considered candidates for production. This type of model requires some form of a blocking mechanism, such as a language tag on each word along with a checking mechanism to ensure that only words from the target language are selected.

By contrast, production models with a language-nonspecific selective mechanism (e.g., Poulisse & Bongaerts, 1994; Hermans, Bongaerts, de Bot, & Schreuder, 1998) assume that words from the nontarget language are considered candidates for production because the system chooses the most highly activated word regardless of the language to which it belongs. To prevent speech in the nontarget language, this type of model requires that words from the target language be activated to a higher level than words from the nontarget language, or the implementation of a mechanism that suppresses activation of words from the nontarget language. Bilingual production models with language nonselective mechanisms therefore predict that the ease of producing words in the target language is affected by the activation of words in the nontarget language (i.e., the two languages compete).

Conclusion

In sum, various models have been proposed to explain the nature of the bilingual lexicon. These models vary along several important dimensions. The majority of these models are descriptive models, including the revised hierarchical model, the word association and concept mediation models, the distributed feature and representation models, the distributed lexical/conceptual feature model, the BIA+ model, BIMOLA, and the word production models. The few mathematically formalized models include the BIA model, SOPhIA, and DevLex-II. The revised hierarchical model, the distributed lexical/conceptual feature model, and DevLex-II have specifically been used to describe changes as a function of increased second language proficiency. The word association model and the revised hierarchical and

distributed lexical/conceptual feature models (for early proficiency) propose indirect access to meaning from the second language. Some other models assume that words in both languages have equivalent access to meaning (the concept mediation model, the distributed feature and representation models, SOPhIA, and the word production models), and yet others do not directly address meaning representation (BIA+ and BIMOLA). All of these models share the feature that they have helped to advance our understanding of several core issues in the study of the bilingual lexicon.

Form-Focused Instruction

LAURA COLLINS

The term *form-focused instruction* describes any pedagogical practice undertaken by second language (L2) teachers with the goal of drawing their students' attention to language form. The "form" may consist of phonological (sound), morphosyntactic (word form and word order), lexical, pragmatic, or orthographical aspects of language. The instruction may be intensive, targeting a specific language feature or set of features, or it may be extensive, addressing a range of problem areas as they arise. The instruction may also vary along a continuum of explicit to implicit techniques and may involve preplanned or spontaneous (incidental) attention to language (both defined in more detail below). The concept has not always been understood in such broad terms, but Ellis's (2001) definition, offered in his introduction to the anthology *Form-Focused Instruction and Second Language Learning*, is the one that is increasingly adopted in contemporary scholarship on L2 teaching and learning.

The term owes its origin to a distinction, first articulated by Long (1991), between *focus on form* and *focus on forms*. The latter, frequently referred to as "traditional grammar teaching," typically describes a teaching approach that follows a structural syllabus focused on a predetermined list of language forms (e.g., articles, verb tenses, prepositions, etc.). In contrast, *focus on form* describes pedagogy in which some attention to language form is integrated within an overall approach focused primarily on communicating and understanding messages in the L2 (e.g., during a discussion of a recent field trip, the teacher provides some guidance on the use of past verb forms). While the attention to form in both approaches results in reflection on language as an object, Doughty and Williams (1998) note that "focus on form *entails* a focus on formal elements of language, whereas focus on forms is *limited* to such a focus, and focus on meaning *excludes* it" (p. 5, emphasis in the original).

Following the publication of Long's (1991) seminal paper, the term "form-focused instruction" initially appeared in the literature as an equivalent of "focus on form" (Spada, 1997). The conceptualization of focus on form, however, quickly moved beyond Long's more restricted notion of a spontaneous, reactive response of a teacher to a learner's error or gap in knowledge, typically in the form of feedback, to encompass preplanned or proactive communicative activities that address observed problem areas for specific populations of learners (e.g., Doughty & Varela, 1998). A further distinction which has emerged is the notion of "preemptive" form-focused instruction, in which teachers anticipate potential problem areas prior to or during a communicative activity (Ellis, Basturkmen, & Loewen, 2001), as opposed to reacting to actual attested areas of difficulty, either immediately or in subsequent lessons. For some scholars, however, preemptive pedagogy does not respect the "problematicity" criterion (Williams, 2005) (i.e., an instructional response to actual learner need), seen to be an essential component of focus-on-form episodes.

More recently, the scope of form-focused instruction (hereafter referred to as FFI) has broadened further such that focus on form (however it is defined) and focus on forms are now both considered to be types of FFI by many scholars, although certainly not by all. Indeed, some have argued for the preservation of the distinction through the use of separate terms, such as "formS-focused instruction" and "FonF instruction" (e.g., Doughty

2 FORM-FOCUSED INSTRUCTION

& Williams, 1998, p. 4; see also Doughty, 2004). The consequence of the “varied interpretations and plethora of rather similar terms” (Williams, 2005, p. 671) that have arisen is that any discussion or empirical investigation of the different issues associated with FFI typically begins with a clear statement of the intended meaning of the term.

There are a number of theoretical and empirical topics related to FFI that have received attention in the applied linguistics literature. In the 1990s a fundamental issue in the North American research context was whether FFI would lead to measurable learning gains, as part of a larger debate over the role of instruction in L2 acquisition. As research showing some benefits for such an approach across a range of languages, learners, and instructional contexts has accumulated, the attention has shifted to specific aspects of FFI, such as the assessment of the relative effectiveness of different types of FFI. One dimension involves examining the degree of explicitness of the attention to language. On the more implicit end of FFI are techniques employed to “boost” the input learners are exposed to, such as seeding written or oral input or both with examples of the target forms (*input flooding*; e.g., Trahey & White, 1993; Bell & Collins, 2009), highlighting the forms in written text to make them more salient (*textual enhancement*; e.g., White, 1998), or restatements of learners’ utterances with the errors repaired (*recasts*; e.g., Lyster & Ranta, 1997). More explicit techniques include statements of rules or patterns (e.g., VanPatten, 2004), with some research focused on whether this is best done inductively, where learners induce the rules or patterns from input, or deductively, where learners apply rules they are given in practice activities (e.g., Erlam, 2003). Other examples of explicit FFI are the use of comparisons between learners’ first language and the L2 (e.g., White, Muñoz, & Collins, 2007), and forms of feedback which elicit attempts at utterance repair on the part of the learners (*prompts*; e.g., Ammar & Spada, 2006). Although Norris and Ortega’s (2000) meta-analysis found more evidence in support of explicit form-focused approaches, to date there has been far less research attention paid to implicit types of instruction and to measuring implicit types of knowledge (Doughty, 2004). This is thus an area for future research. Another under-researched area is the timing of FFI; that is, whether the instruction is more effective if the form focus is integrated into communicative activities or conducted separately in isolated lessons (Spada & Lightbown, 2008). The theoretical issue here is whether the cognitive process of mapping form and meaning, and the subsequent retrieval of this learned information in real-time communication (*transfer-appropriate processing*), are facilitated by a simultaneous focus on form and meaning during the same instructional activity.

Other issues that continue to motivate research on FFI include whether FFI is more effective or necessary for certain forms than for others, investigated in both laboratory (e.g., DeKeyser, 1995) and classroom contexts (e.g., Spada, Lightbown, & White, 2005); the timing of FFI with respect to learners’ developmental readiness (e.g., Mackey & Philp, 1998); and the interaction between different FFI approaches and individual differences among learners such as working memory and analytical ability (e.g., Robinson, 1997). Although there has also been research demonstrating the feasibility of engaging in FFI with young L2 learners (e.g., Harley, 1998; Bouffard & Sarkar, 2008), the interaction between the individual variable of age and FFI is yet another area that merits further investigation.

Formulaic Language and Collocation

NORBERT SCHMITT

It is now clear that vocabulary typically behaves not as single words which are held together by syntax, but rather has a strong tendency to occur in multiword phraseological units. Formulaic language is very common in language overall, in both spoken and written modes. For example, Erman and Warren (2000) calculated that 52–8% of the language they analyzed was formulaic, and Foster (2001) came up with a figure of 32% using different procedures and criteria. Biber, Johansson, Leech, Conrad, and Finegan (1999) found that around 30% of the words in their conversation corpus consisted of lexical bundles, and about 21% of their academic prose corpus. Howarth (1998) looked at frequent verbs in a social science/academic corpus and found that they occurred in either restricted collocations or in idioms in 31–40% of the cases. This research convincingly shows that formulaic language is no mere peripheral feature of language, but rather is a ubiquitous and essential feature of how it is used.

The Functions of Formulaic Language

Being such a big part of language, it is not surprising that formulaic language as a phenomenon is not homogeneous (although many researchers treat it as if it is). It realizes different purposes in language use, including transacting routinized meanings (*that'll be X dollars* = typical way for American shopkeepers to state the cost of a bill), and smoothing social interaction (*yeah, it is* = a routinized way of agreeing with an interlocutor's assertion) (Schmitt & Carter, 2004). It also provides the building blocks upon which one can create more extended strings of language (e.g., with collocations (*valid point*)), and with lexical bundles: *it should be noted that* = a standard academic phrase which highlights a point of interest (Biber et al., 1999).

Moreover, one reason that formulaic language is so widespread is that it lexicalizes a wide number of referential, textual, and communicative functions in discourse. It can be used to express a concept (*get out of Dodge* = get out of town quickly, usually in uncomfortable circumstances), state a commonly believed truth or advice (*too many cooks spoil the soup* = it is difficult to get a number of people to work well together), provide phatic expressions which facilitate social interaction (*nice weather today* is a nonintrusive way to open a conversation), signpost discourse organization (*on the other hand* signals an alternative viewpoint), and provide technical phraseology which can transact information in a precise and efficient manner (*2-mile final* is a specific location in an aircraft landing pattern) (Schmitt & Carter, 2004). Likewise, Nattinger and DeCarrico (1992) argue that formulaic language fulfils the functions of maintaining conversations (*How are you?*, *See you later*), describing the purposes for which the conversations take place (*I'm sorry to hear about X*, *Would you like to X?*), and realizing the topics necessary in daily conversations (*When is X?* (time), *How far is X?* (location)). In fact, one might suppose that for every conventional activity or function in a culture, there will be associated phrasal vocabulary. If that is so, there are bound to be a large number of formulaic expressions, perhaps even a larger number than that of single-word vocabulary.

Formulaic sequences become particularly important in language use when we consider their pragmatic value. For instance, they are very often used to accomplish recurrent communication needs. These recurrent communicative needs typically have conventionalized language attached to them, such as *I'm (very) sorry to hear about . . .* to express sympathy and *I'd be happy/glad to . . .* to comply with a request (Nattinger & DeCarrico, 1992, pp. 62–3). Because members of a speech community know these expressions, they serve as a quick and reliable way to achieve the desired communicative effect. Formulaic sequences also realize a variety of conversational routines and gambits and discourse objectives (Coulmas, 1979, 1981). They are typically used for particular purposes and are inserted in particular places in discourse. For instance, formulaic sequences regularly occur at places of topic-transition and as summaries of gist (Drew & Holt, 1998). Most (all?) conventional speech acts are realized by families of formulaic language and not normally by original expressions (*I'm very sorry* versus *I am feeling apologetic toward you*). Overall, understanding the pragmatic role of formulaic language can tell us much about the nature of interaction (McCarthy & Carter, 2002).

Moreover, formulaic sequences do more than just carry denotative meaning and realize pragmatic function. They can often have a type of register marking called *semantic/collocational prosody* (Stubbs, 2002; Sinclair, 2004; Hunston, 2007). This is often negative—for example, the verb *cause* frequently has a negative evaluation (*cause pain, cause inflation*). However, semantic prosody can also be positive, as in collocations that form around the word *provide* (*provide information, provide services*). This semantic prosody is one means of showing a speaker/writer's attitude or evaluation. For example, their stance can be indicated concerning the knowledge status of the proposition following the formulaic item (*I don't know if X* indicates uncertainty about X), their attitude toward an action or event (*I want you to X* shows a positive attitude toward this action), and their desire to avoid personal attribution (*it is possible to* avoids a directly attributable suggestion) (Biber, Conrad, & Cortes, 2004). Likewise, the choice of formulaic sequences can reflect an author's style and voice (Gläser, 1998). Formulaic sequences can also be used to encode cultural ideas, as Teliya, Bragina, Oparina, and Sandomirskaya (1998) have demonstrated for Russian.

Acquisition of Formulaic Language

The learning of individual words is incremental and each word has its own particular learning burden (Nation, 1990; Schmitt, 2000), and there is no reason to believe that formulaic language is any different in this respect. This would suggest that many formulaic sequences are partially known for a number of exposures until the point where they become mastered. Certainly, some L1 acquirers learn and use formulaic sequences before they have mastered the sequences' internal makeup. For example, they sometimes seem to acquire an initial phonological mapping of formulaic sequences proceeding from the whole to the individual parts, but with some elements still incompletely grasped, especially the unstressed phonemic constituents (e.g., Peters, 1977; Plunkett, 1993). In L1 acquisition, children with expressive tendencies (having interactional goals; focusing on the social domain) were more likely to learn formulaic expressions than children who had tendencies to name things with individual words (Nelson, 1973). This points out the importance of formulaic language in promoting the kind of social integration which promotes language acquisition in general. In L2 acquisition, formulaic sequences are also relied on initially as a quick means to be communicative, albeit in a limited way. This can lead to faster integration into a peer group, which can result in increased language input. Wong Fillmore (1976) found this was the case with five young Mexican children trying to integrate into an English-medium school environment. She identified eight strategies the children used, and at least three of them directly involved formulaic language:

- Give the impression, with a few well-chosen words (phrases), that you speak the language.
- Get some expressions you understand, and start talking.
- Look for recurring parts in the formulas you know.

The use of formulaic sequences enabled the realization of these strategies even though the children's language capabilities were quite limited. Furthermore, the use of formulaic sequences to facilitate language production is not restricted to L2 children. Schmidt's (1983) study of Wes is a good example of the phenomenon in L2 adults; Wes's speech is filled with formulaic language as a means of fulfilling his desire to be communicative, but not necessarily accurate. Additionally, Adolphs and Durow (2004) found that the amount of social integration into the L2 community (with presumably a commensurate need to be communicative in the L2) was linked to the amount of formulaic language produced in the speech of L2 postgraduate students.

But formulaic sequences may provide language learners with more than an expedient way to communicate; they might also facilitate further language learning. For L1 learners, it has been proposed that unanalyzed sequences provide the raw material for language development, as they are segmented into smaller components and grammar (Peters, 1983). For example, when a child realizes that the phrase *I wanna cookie* (previously used as a holistic unit) is actually *I wanna* + *noun*, he or she gains information about the way syntax works in the language, as well as the independent new word *cookie*. A number of studies suggest that some children segment formulaic sequences into smaller units, and in doing so, advance their grammatical and lexical knowledge (see Wray, 2000, for one review). It seems that formulaic sequences serve the same purpose for L2 learners (e.g., Myles, Hooper, & Mitchell, 1998; Bardovi-Harlig, 2002). Moreover, there is little doubt that the automatic use of acquired formulaic sequences allows chunking, freeing up memory and processing resources (see Kuiper, 1996; and Ellis, 1996, who explores the interaction between short-term and long-term phonological memory systems). These can then be utilized to deal with conceptualizing and meaning, which must surely aid language learning.

L1 children are exposed to many formulaic sequences in their input, but how do they decide what to analyze and what to keep at the holistic level? Wray (2002) suggests that a "needs-only analysis" is the mechanism. Rather than segmenting every sequence into the grammar system, children will operate with the largest possible unit, and only segment sequences when it is useful for social communication. Thus the segmentation process is driven by pragmatic concerns (communication), rather than an instinctive urge to segment in order to push grammatical and lexical acquisition. The default would be to not analyze, and to retain holistic forms. Thus children maintain many formulaic sequences into adulthood, even though the components of those sequences are likely to be stored individually as well (perhaps being acquired from the segmentation analyses of other formulaic sequences). This suggests that dual storage is the norm. (It is useful to note that the notion of "holistic storage" is actually a metaphor. There is yet no conclusive evidence as to whether formulaic sequences are actually stored in memory as wholes, or whether they are simply computed very efficiently in a manner which gives them the characteristics of holistic units.)

Of course, relying on holistic versus analytical approaches to language acquisition and use is not an either/or proposition, and children will use both approaches in varying degrees. However, Wray and Perkins (2000) and Wray (2002) suggest that the relative ratios between the approaches may change according to age. During phase 1 (birth to around 20 months), the child will mainly use memorized vocabulary for communication, largely learned through imitation. Some of this vocabulary will be single words, and some will consist of sequences. At the start of phase 2 (until about age 8), the child's grammatical awareness begins, and the proportion of analytic language compared to holistic language increases, although with overall language developing quickly in this phase, the

amount of holistically processed language is still increasing in real terms. During phase 3 (until about age 18), the analytic grammar is fully in place, but formulaic language again becomes more prominent. "During this phase, language production increasingly becomes a top-down process of formula blending as opposed to a bottom-up process of combining single lexical items in accordance with the specification of the grammar" (Wray & Perkins, 2000, p. 21). By phase 4 (age 18 and above), the balance of holistic to analytic language has developed into adult patterns.

The course of formulaic sequence development is more difficult to chart in L2 learners. Typically there is early use of formulaic sequences, often after a silent period. As learners' proficiency improves, there is a reasonable expectation of language which is more accurate and appropriate. In natives, this is achieved to a large extent through the use of formulaic sequences (e.g., Nattinger & DeCarrico, 1992). Unfortunately, the formulaic language of L2 learners tends to lag behind other linguistic aspects (Irujo, 1993), but this is not so much a case of the amount of formulaic language use, but rather a lack of native-like diversity. This is probably largely due to a lack of sufficient input. Irujo (1986) suggested that one specific class of formulaic language (idioms) is often left out of speech addressed to L2 learners, leading to a lack of idioms in learner output. More recently, Durrant and Schmitt (2009) show that a more general type of formulaic language (collocations) seems to be tuned to frequency, with L2 learners producing frequent, but not infrequent, collocation pairs. Furthermore, Siyanova and Schmitt (2008) showed that spending a year in an English-speaking country (with presumably a great increase in the amount of L2 input) led to better intuitions of collocation.

However, it may not be just the *amount* of input that is crucial, but also the *quality*. Siyanova and Schmitt (2007) found that the amount of exposure to native-speaking environments did not have an effect on the likelihood of using the multiword verbs. This, however, might be explained by Adolphs and Durow's (2004) findings that sociocultural integration was the key to their case-study learner's acquisition. This suggests that it may not be exposure per se that is important, but the kind of personalized and engaging exposure that presumably occurs in a socially integrated environment.

The nature of formulaic language and its acquisition is likely to become of ever-greater interest as the field turns to more pattern-based models of language acquisition—e.g., pattern grammar (Hunston & Francis, 2000) and usage-based theory (Tomasello, 2003)—which posit that the human facility for language learning is based on the ability to extract patterns from input, rather than being under the guidance of innate principles and parameters which determine what aspects of grammar can and cannot be acquired (see Langacker, 1987; Bybee, 1998; Ellis, 1996, 2002). For example, this line of thinking suggests that we learn the letter sequences which are acceptable in a language (the consonant cluster *sp* can be word-initial in English, but *hg* cannot) simply by repeatedly seeing *sp* at the beginning of words, but not *hg*. This learning is implicit, and may not be amenable to conscious metalinguistic explanation. Of course, learners may eventually reach the point where they can declare a "rule" for this consonant clustering, but the rule is an artifact of the pattern-based learning, rather than the underlying source of learning (e.g., Bod, 2006).

This pattern-based learning also works for larger linguistic units, such as the way in which sequences of morphemes combine to form words (*un-question-able*, *un-reli-able*, *un-fathom-able*). Moving to words, we gain intuitions about which words collocate together and which do not (*blonde hair*, **blonde paint*; *auburn hair*, but only for women, not men). Many of these collocations must be based solely on associative pairing, because there is often no semantic reasoning behind acceptable/nonacceptable combinations (**blonde paint* makes perfectly logical sense). Neither are most collocations likely to be learned explicitly, because they are not normally taught, and even if they are, only possible cases are illustrated, not inappropriate combinations. Longer formulaic strings, which are also based on

patterns rather than rules, seem to fit very nicely with such sequence-based models of acquisition as well. Time will tell whether this kind of model best captures the mechanics of formulaic sequence acquisition (and that of language in general). However, one thing seems certain; given the increasingly evident importance of formulaic sequences in language use, convincing explanations of the mechanics of their acquisition must become an essential feature of any model of language acquisition.

Non-Native Use of Formulaic Language

Formulaic language is very widespread in L1 language use (e.g., Biber et al., 1999; Erman & Warren, 2000; Foster, 2001). But what about non-native speakers? There is a widespread feeling that formulaic language is especially problematic for L2 learners, and its lack/misuse is a major reason why L2 output can feel unnatural and non-native-like, at least in their compositions (most research on formulaic language has focused on written discourse). Research has only partially supported this impression. We can look at non-native mastery of formulaic language along at least three dimensions: amount of use, accuracy/appropriacy of use, and quality/speed of the underlying formulaic intuitions. There is a growing literature about the first two dimensions, but only embryonic research on the last. Let us look at each dimension in turn.

Amount of Use

It is easy to assume that that problem with non-natives is that they simply do not use as much formulaic language as natives. This is largely incorrect, although there can be an element of avoidance (Laufer & Eliasson, 1993; Laufer, 2000). A series of studies have found that L2 usage depends on *which* formulaic sequences one is focusing on. It is now clear that non-natives actually use *more* of certain favorite formulaic sequences which they know well and tend to overuse as “safe bets,” compared to natives (Granger, 1998; de Cock, 2000; Foster, 2001). Conversely, they use *fewer* of other sequences, presumably because they do not know them as well and are not as confident in their use (e.g., Granger, 1998; Howarth, 1998; Foster, 2001). One type of formulaic sequence which seems to be particularly underused is multiword verbs. For example, Altenberg and Granger (2001) found that their EFL learners had great difficulty with the verb *make*, especially the delexicalized uses, such as *make a decision* and *make a claim*. This is particularly problematic as high-frequency verbs like *make*, *look*, and *do* are used in numerous formulaic sequences. Interestingly though, Granger, Paquot, and Rayson (2006) compared formulaic sequences in a one-million-word native-speaker academic corpus and one million words from the ICLE learner corpus (International Corpus of Learner English) and found more cases of overused formulaic sequences than underused ones.

Durrant and Schmitt (2009) go some way in explaining which formulaic sequences are overused and which underused. Using a corpus composed of written academic output from Turkish and Bulgarian university EFL students and a mixed group of international university students studying in the UK, they found that these students tended to use frequent premodifier-noun collocations at a rate similar to native students. (Congruently, Siyanova and Schmitt (2008) found that their non-natives used adjective-noun collocations in frequencies similar to natives.) These are the kind of collocations which are identified by measures which give a relatively heavy weighting to frequency, such as the *t* score statistic (*good example*, *long way*, *hard work*). However, the non-natives produced many fewer low-frequency collocations (*densely populated*, *bated breath*, *preconceived notions*), even though these combinations are very strongly linked. (This kind of lower-frequency, but tightly bound, collocation is better identified by the mutual information [*MI*] collocation statistic).

Because of their strong ties, and relative infrequency, they are likely to be especially salient for natives, and so their absence in non-native output is particularly noticeable. The authors conclude that the lack of these “MI” collocations is one key feature which distinguishes native from non-native production. In terms of acquisition, L2 learners seem to be able to acquire and use the collocations which appear frequently, but do not seem to pick up as many nonfrequent collocations, whose individual component words may also be infrequent in themselves. This is highly suggestive of the role of frequency in the acquisition process. This is supported by Ellis, Simpson-Vlach, and Maynard (2008), who found that for natives, it is predominately the *MI* of a formulaic sequence which determines processability (as measured by reaction-time experiments), while for non-natives, it is predominately the *frequency*.

Accuracy/Appropriacy of Use

Oppenheim (2000) found that much of the language which her non-native subjects produced in consecutive speeches on the same topic consisted of the same recurrent word strings, but that most of these were idiosyncratic in comparison to native-speaker norms. Thus, just because L2 learners produce formulaic language, it is not necessary formulaic in the sense of matching what natives would produce.

Nesselhauf (2003, 2005) gives us some idea of how formulaic language can be “non-native.” She extracted 1,072 English verb–noun combinations from 32 essays in the ICLE written by German university students. Almost one-quarter of these collocations were judged to be incorrect; moreover, the L1 was deemed to be an influence in 45% of the errors. However, the incorrect usage was often the result not of combining words in an unconventional way, but of using conventional word pairs in ways which are not appropriate (Nesselhauf, 2005). This suggests that the difficulty learners have is not only that of learning which words go together, but also learning how to employ the chunks they know. Therefore, at least for the more frequent collocations, the problem may not be so much in the *amount* of formulaic language learners use, but in using the formulaic sequences they know *appropriately* in the right contexts.

Quality/Automaticity of Intuitions of Formulaic Language

So formulaic sequences can be overused, underused, and misused by non-native writers (most of this research has been based on analysis of written text), but they are definitely used; there is no question that L2 output is devoid of formulaic language. But how good are the non-native intuitions of this language? There is little research which addresses this; however, three studies found that non-native intuitions were not as well developed as native intuitions.

Siyanova and Schmitt (2008) directly compared native and non-native judgments of the frequency of high-frequency, mid-frequency, and low-frequency adjective–noun collocations on a six-point Likert scale. They also measured how long it took to make these judgments. They found that the natives had fairly good intuitions of the collocation frequency, and that they made their frequency judgments relatively quickly. Compared to these native norms, the non-natives judged the high-frequency collocations as being lower frequency, and judged the low-frequency collocations as being much higher. Furthermore, natives were able to distinguish the frequency difference between mid- and high-frequency collocations, but the non-native as a whole were not. Interestingly though, the non-natives who spent a year or more in an English-speaking country were able to make this distinction. Also, the non-natives took much longer to make their frequency judgments. Taken together, Siyanova and Schmitt conclude that the non-natives’ intuitions were not as developed as the natives’, nor were they as automatized.

Hoffman and Lehmann (2000) elicited native and non-native speakers' intuitions regarding 55 collocations from the BNC with high log-likelihood scores (mainly adjective–noun and noun–noun pairs). Respondents were presented with each node in a questionnaire, and were asked to supply the collocates. On average, the native speakers supplied the “correct” collocate in 70% of cases, which, like the results in Siyanova and Schmitt, indicates relatively good intuitions by the natives. The non-natives did far less well, achieving an average accuracy of only 34%. This shows a major gap between the native and non-native intuitions, although in absolute terms, the non-native results (producing about one third of the collocates) still indicate considerable knowledge.

This poorer intuitive mastery is reflected in learners' production. While natives tend to resort to formulaic language to get through time-pressurized communicative situations, non-natives do not seem to make greater use of formulaic language in such cases, either in speech or writing (Foster, 2001; Nesselhauf, 2005). In terms of speech, non-natives tend to use many recurrent dysfluency markers (such as filled pauses and hesitation markers), although it seems that extensive interaction with native speakers enables them to overcome this (de Cock, Granger, Leech, & McEnery, 1998; Adolphs & Durow, 2004). However, in terms of writing, neither amount of use nor accuracy of collocation appears to increase with time spent in an English-speaking country (Yorio, 1980; Nesselhauf, 2005). So, although a year or more spent in an English-speaking country can lead to better *intuitions* of collocation (Siyanova & Schmitt, 2008), it seems difficult to extend this into increased *production* of formulaic language.

Conclusion

It seems that mastery of formulaic language takes a long time to acquire and is a hallmark of the highest stages of language mastery. Language testers have picked up on this and often include items which focus on phraseology in their highest-level examinations. Formulaic language is an important element of language overall, perhaps *the* essential element. Research into it is only now gaining momentum, but given its ubiquitousness and demonstrated processing advantages, it looks to be one of the most important areas of inquiry in the applied linguistics field for the foreseeable future.

Formulaic Sequences

ALISON WRAY

Definition

A “formulaic sequence” is broadly defined as a string of words with a meaning or function different from that of its component parts and which, for that reason, is hypothesized to be processed holistically (Wray, 2002, p. 9). Examples include idioms (e.g., *to take someone to the cleaners*, meaning ‘to charge someone too much money’), common social routines (e.g., *mind how you go*, which is used for leave-taking), and many common collocations, including multiword verbs (e.g., *put down*, with at least two holistic meanings, ‘denigrate’, ‘euthanize’; *come by*, meaning ‘acquire’; *go and* *VERB*, meaning ‘*VERB* unexpectedly or unadvisedly’ (as in ‘he went and paid for me to get in’; ‘don’t go and catch a cold, will you’).

While the types above are relatively uncontentious, debate occurs regarding expressions whose holistic meaning is hardly different from their compositional one. For example, *have a nice day* carries, in its US usage at the end of customer service encounters, strong contextual and pragmatic overtones associated with the whole expression. Yet it also breaks down semantically. Judging whether such examples should count as formulaic depends on the researcher’s preferred theory. Theories proposing that a word string *first* develops a holistic meaning different from its literal meaning, and *then* becomes holistically processed, can treat *have a nice day* as moving toward formulaicity but not yet there. However, theories such as “needs only analysis” (see below) do not require a word string to be non-compositional before it is holistically processed, and can view *have a nice day* as formulaic despite its compositionality, since it carries features of meaning and function that are tied to the string as a whole.

Functions

A major role of formulaic sequences seems to be enhancing fluency in relatively routine situations (e.g., Pawley & Syder, 1983), so as to reduce the overall processing load. Using prefabricated expressions is only appropriate when we are not trying to say something new. However, even when we are, a partly prefabricated frame that we complete with novel information can still reduce processing. In fact, this mix can actually highlight what is new, as Kuiper (1996) observed in auctions. Research on oral traditions of storytelling, reviewed and discussed in Wray (2008a, chap. 4), shows how performers can blend the conventional content of a culturally recognized piece of literature with their own unique contribution as creative artists.

Evidence

Several types of evidence indicate that formulaic sequences are indeed holistically processed. In clinical linguistics it has long been known that some socially motivated expressions survive in acquired language disorders (e.g., Wray, 2010; for reviews, see Van Lancker, 1987; Wray, 2002, chaps. 12–14; Wray, 2008b). This suggests that these expressions do not

2 FORMULAIC SEQUENCES

require online assembly, and perhaps are stored in, or accessed from, areas of the brain other than the left hemisphere language centers.

The fluency with which formulaic sequences are produced is also indicative of holistic—or at least privileged—production processing, and a range of other phonological characteristics, including faster pace, underdefined weak syllables, assimilation within the word string and little if any at the boundaries, and a reduced number of tone units compared to an equivalent novel expression, are also consistent with holistic processing (Lin, 2010). Research that tracks eye movement during reading (e.g., Conklin & Schmitt, 2008; Columbus, 2010) and electrical activity in the brain (e.g., Tremblay, Derwing, Libben, & Westbury, 2011) offers independent confirmation of this observation, as well as providing opportunities for a more fine-grained differentiation between subtypes of formulaic sequence.

Research Foci

Current issues in research include the question of whether formulaicity is absolute or is graded on a continuum (for a discussion of the issues, see Wray, 2002, pp. 62–5), how best to identify formulaic sequences in spoken and written text (e.g., Wray, 2002, chaps. 2–3; Wray, 2008a, chaps. 8–9; Wray, 2009), and the relationship between formulaicity and frequency. The first of these questions is important because without a continuum model it is difficult to account for the native speaker’s collocational knowledge. Opinion varies as to whether collocations count as formulaic language. Is it plausible to suppose that a native speaker stores specific knowledge of all the different nativelike collocations, particularly since collocations are tendencies rather than definite associations? There are good reasons to hypothesize that collocational knowledge is based on observations of frequency of co-occurrence in input, even though frequency is not a panacea in accounting for formulaicity (see below).

Regarding identification, it is easy to fall into circularity, using examples to establish definitions, and definitions to identify examples. Furthermore, it remains difficult entirely to obviate human judgment, even in corpus-based approaches. So interest has focused on how to minimize subjectivity and maximize replicability. The new approaches for adducing independent evidence of holistic processing (see “Evidence” above) are a promising way to ground the claims of formulaicity, providing a point of reference for explorations of the more difficult or borderline cases.

As for the question of frequency, the availability of large corpora and of sophisticated search tools has led to considerable research activity focused on identifying the most frequently occurring multiword strings, normally termed “lexical bundles” (e.g., Biber, 1988). Although there are, on the one hand, good reasons for arguing that frequent word strings are important for our understanding of how we construct text, and, on the other, that a holistically processed word string, being easier to produce, is likely to be used more often than a nonformulaic equivalent, it still does not follow that the most frequent strings are always holistically stored, nor that every holistically stored string will be frequent. Many of the word strings identified as lexical bundles in corpora are implausible as holistic units (e.g., *I think I*), while many plausibly holistic units (e.g., *don’t you dare VERB*; *kick the bucket*) are not frequent in absolute terms, because the meaning (or nuance of meaning) they convey is not called for all that often.

Theoretical Issues

As some of the examples used above indicate, formulaic sequences are understood often to be only partly fixed, so they include one or more gaps for morphological or lexical variation. Whereas it would be impossible for humans to store enough fully lexicalized

multiword expressions to handle every message they might hear or need to express, the storage of partly lexicalized frames presents a viable alternative to grammatical models in which only morphemes and words are lexically stored, with multiword strings always constructed by rule.

Broadening the range of lexical units stored in memory to include items several words long does not conflict with the notion that most words also have their own form–meaning representation in the lexicon. It does, however, downgrade the assumption that words are always primary and special in psycholinguistic terms. As a result, it becomes easier to explain the difficulty of pinning meaning onto particular words without reference to the other words they occur with, including grammatical particles and many words that are collocate-dependent (e.g., *take* in *take care of*, *take account of*, etc; *red* in the context of *hair*, *wine*, *meat*). It also helps explain observations made in grammatical theory, such as that verb patterns contain meaning independent of the identity of the verb (Hunston & Francis, 2000). For instance, the pattern V NP NP, as classically exemplified by *he gave Mary a book* and *I'll send you a letter*, seems to convey the meaning of doing something for a beneficiary even when a different verb, that does not normally have that meaning, is used: *they felled him a tree*; *can you wash me a plate?* In addition to Hunston and Francis's pattern grammar, there are strong points of similarity here with construction grammar (Goldberg, 2006), usage-based grammar (e.g., Tomasello, 2003), and emergent grammar (e.g., Hopper, 1998).

Yet, because humans clearly do have the capacity to construct utterances on a completely novel basis, using grammatical rules, it behoves researchers into formulaic language to explain why formulaic sequences exist. Wray's (2002, 2008a) "needs only analysis" model proposes that, during language acquisition, infants associate a meaning with the largest unit they can (often several words long), only breaking the material down further if they need to. They are thereby able to produce back to their carers, with relatively little effort, complete messages that are likely to be easily recognized and understood. Noticing where variation does occur in input, the child gradually identifies the loci of variable items, without discarding the fixedness of others, which creates the most effective balance between saying what one needs to say, and saying it in the way others would say it.

Wray's (2002) model proposes that the underlying drive in the child is to manipulate others to provide for them physically, mentally, and emotionally, and this accounts for the preoccupation with expressing ideas in the way most likely to be correctly interpreted. That is, the child seeks not only to keep his/her own processing to a minimum, but also that of the hearer. It remains in our interests into adulthood to use the language that hearers are most likely to understand, which explains why we often adapt our patterns of language as we move from speech community to speech community.

Thus, two side effects of "needs only analysis" are a developing sensitivity to the language patterns of those with whom we affiliate, which provides strong social bonds and anchors identity, and a strong intuition about what "sounds right"—a capacity that filters the total of potential grammatical sentences in the language, to create the subset actually said by native speakers.

This idea meshes well with Sinclair's (1991, p. 114) proposal that we process words as groups if we can (the idiom principle), and only engage with them individually when we need to (the open-choice principle). It explains how word groups can sustain details of meaning that are not found in the separate components, and why certain word groups are preferred over others with similar meaning, as corpus research demonstrates.

Formulaic Sequences in SLA

It is the sensitivity to the idiomatic subset of the grammatical possibilities in a language that seems most difficult for adult L2 learners to master, particularly in contexts with limited opportunities to hear, and little motivation to affiliate with, native speakers.

4 FORMULAIC SEQUENCES

The needs of post-childhood learners are different from those of young children, and include, often, that of sustaining their own L1-centered identity. They also have, it seems, a need—whether caused by maturation, culture, education, or literacy—to “manage” the L2 using smaller units and rules, which will tend to prevent them noticing and learning the formulaic sequences that constitute idiomaticity (Wray, 2002).

Not surprisingly, researchers worldwide are interested in finding out the best way to overcome these hurdles and enable adult L2 learners more closely to approximate native-like knowledge and performance. Key questions include: How can formulaic sequences be effectively introduced in the classroom (for one discussion, see Wray, 2000)? Does a focus on genuine communicative tasks offer particular opportunities for mastering routine expressions (e.g., Gatbonton & Segalowitz, 1988)? Should the form of formulaic sequences be explicitly studied, or deliberately ignored? Researchers in China have demonstrated that text memorization can improve general proficiency (Ding, 2007; Dai & Ding, 2010), though clearly an over-reliance on memorized material could bring its own problems.

The Future

The past 15 years of research into formulaic sequences have generated a number of claims that future work needs to confirm or challenge empirically. For instance, it is commonly asserted that native speakers know a huge number of formulaic sequences but, so far, specific quantification has been elusive. Similarly, it is generally assumed that our knowledge of formulaic sequences is essentially stable, but this remains unsubstantiated. In addition, formulaic sequences are now increasingly recognized by linguists as a central, rather than peripheral, facet of our linguistic knowledge, which means they need to be accommodated in theory, and taken into account when lexis and grammar are under investigation.

Fossilization

ZHAOHONG HAN

What Is Fossilization?

Fossilization is deemed a central characteristic of second language (L2) acquisition (Selinker, 1972; Bley-Vroman, 1989; Long, 2003). Since its inception, the construct of fossilization has sparked a great deal of interest from both L2 researchers and teachers, although the concept is not always well understood or applied.

Since the late 1960s, the field of second language acquisition (SLA) has been preoccupied with incomplete or divergent acquisition. In particular, attention has been drawn to the fact that “[Learners] achieve very different degrees of language mastery. Few, it seems, achieve native-like proficiency. Some stop (or, to use Selinker’s [1972] term, ‘fossilise’) at a very elementary level. Others come between the two extremes” (Perdue, 1993, p. 8). The issue of fossilization has thus come to the fore, referred to first by Selinker (1972, p. 215) as a psycholinguistic phenomenon manifested as

linguistic items, rules, and sub-systems which speakers of a particular L1 [first language] tend to keep in their IL [interlanguage] relative to a particular TL [target language], no matter what the age of the learner or amount of explanation and instruction he receives in the [target language].

Following Selinker’s initial formulation, a plethora of definitions and applications of the term have emerged, which collectively point to several attributes of fossilization, such as (a) persistent deviance; (b) resistance to external influence, including explicit instruction and corrective feedback; and (c) being out of the learner’s control. However, it also appears that most of these definitions have missed out on the key premises upon which fossilization was initially predicated (Selinker & Lamendella, 1979, p. 373):

The conclusion that a particular learner had indeed fossilized could be drawn only if the cessation of further [interlanguage] learning persisted *in spite of the learner’s ability, opportunity, and motivation to learn the target language and acculturate into the target society.* (emphasis added)

Synthesizing early and more recent conceptions, Han (2004) updates the definition of fossilization as a process whereby learning ceases in spite of (a) adequate motivation to learn, (b) abundant exposure to input, and (c) plentiful opportunities for communicative practice. Central to the original as well as to the updated definition is that fossilization is *selective* and *local*, rather than global. Han and Odlin (2006, p. 8) have hypothesized that “L2 acquisition will never have a global end state; rather, it will have fossilization, namely, permanent *local* cessation of development” (emphasis added). This hypothesis has been amply supported by research on L2 end-state grammars (see, e.g., Franceschina, 2005; Lardiere, 2007). Overall, fossilization has so far been reported for child, adolescent, and adult L2 learners in naturalistic and classroom contexts.

Historically, research on fossilization has largely been descriptive, with its main thrust documenting stabilization of interlanguage forms in individual learners in case studies (for a review, see Han, 2004, 2011). Continuing that tradition, contemporary research has primarily engaged with two overarching questions: What linguistic elements are prone to fossilization and what drives selective fossilization? Answers to such questions have highlighted the cognitive complexity of (adult) L2 acquisition relative to first language (L1) acquisition and child L2 acquisition.

What Linguistic Elements Are Prone to Fossilization?

According to the fossilization literature, morphosyntactic features prone to fossilization come in two types. The first type concerns so-called “soft” features, which appear to lie at the interface between syntax and semantics, syntax and pragmatics, and syntax and discourse (for discussion, see Sorace, 2005). The second type concerns grammatical functors (Lardiere, 1998; Franceschina, 2005; Han, 2008), such as nominal and verbal inflections and articles. These linguistic features, as research from various theoretical perspectives has demonstrated, are hard to acquire and may permanently defy complete acquisition (Han & Lew, *in press*).

By way of illustration of Type 1 features, Han (2006) reports on a seven-year longitudinal study of two advanced L1-Chinese speakers of L2-English, showing that, despite their high motivation to learn and daily communicative interaction with native speakers of English, the case subjects nevertheless fossilized in their use of English unaccusative verbs. The fossilization manifested itself in persistent conflation of the transitive and intransitive variants of verbs of causative alternation (examples 1a and 1b), its extension to verbs that can only be used intransitively (2a and 2b), and persistent variational use of transitive and intransitive forms (3a and 3b).

(1a) My thinking way has been changed a lot since joining Fanta.

(1b) My English was not improved.

(2a) Gass is arrived.

(2b) Our phone bill arrived this morning.

(3a) Relay event against Listserv is now disappeared.

(3b) We expect that this will gradually disappear.

These problems involve linguistic features putatively at the interface of syntax and semantics (Levin & Rappaport Hovav, 1995). Put simply, the problems concern form–meaning mapping.

With respect to Type 2 features, research from multiple perspectives has provided converging evidence to suggest that grammatical functors constitute a prime area of fossilization (e.g., Lardiere, 2007). Traditionally, grammatical functors as a whole are treated as purely formal features; they are considered noncommunicative or meaningless. Yet research from a cognitive-linguistic perspective has revealed that some (if not all) grammatical functors, in fact, are “soft” (Han, 2008) and, inasmuch as they encode abstract concepts, are similar to the interface features noted above, highly susceptible both to crosslinguistic interference (Slobin, 1996) and to fossilization. What seems to distinguish them from syntactic-interface features (Type 1) is that their acquisition is more contingent upon restructuring of an L1-based conceptual and semantic system than the latter, and, in particular, of L1-based thinking for speaking or writing (Slobin, 1996). For instance, the acquisition of the English plural *-s* morpheme requires, among other things, the knowledge of what to pluralize,

how, and when to pluralize. Of that knowledge structure, the last component has proven the most elusive for L2 learners from certain L1 backgrounds, for example, an L1 that is largely non-inflectional. Indeed, what appears to unite the fossilizability of Type 1 and Type 2 features is that they both involve complex form–meaning–function mappings, the hardest task of all in L2 acquisition (Han & Lew, in press).

The contribution of fossilization research to the general understanding of SLA is by no means confined to identifying a constellation of *acquisitionally complex* features (Han & Lew, in press); it has also illuminated factors driving their incomplete learning.

Why Selective Fossilization?

Research on fossilization has established that fossilization is local and selective; it happens only selectively in certain domains and subsystems, while other parts of the learner system successfully converge on the target (for ample evidence, see Lardiere, 2007). What explains such selectivity?

Han (2004) culled some 50 factors from the literature, broadly categorizing them as environmental, cognitive, neurobiological, and socioaffective factors contributing to fossilization. Two of these factors have garnered most consensus: native-language (NL) influence and biological maturation (or the so-called “critical period” effect). However, it is readily recognized that neither factor alone or in combination can provide a sufficient explanation for the selective character of fossilization.

More recently, assuming that native language, maturation, and universal grammar (UG) all impose constraints of sorts on (adult) L2 acquisition, Han (2009) hypothesizes that it is the interaction between *L1 markedness* (viz., frequency and form–meaning–distribution variability) and *L2 input robustness* (viz., frequency and form–meaning–distribution variability) that leads to selective fossilization. This is illustrated in Figure 1.

According to this selective-fossilization hypothesis, the interaction between L1 characteristics and L2 input conditions portends differential consequences for L2 acquisition. Thus, all things being equal, a given L2 feature may fall in the acquisition zone (Zone II in Figure 1) *if* the L1 counterpart is marked (i.e., infrequent and inconsistent) and *only if* the L2 input is robust (frequent and consistent); conversely, a given L2 feature may fall in the fossilization zone (Zone IV) *if* the L1 counterpart is unmarked (i.e., frequent and consistent)

Figure 1 Selective fossilization © ZhaoHong Han

and *only if* the TL input is nonrobust (i.e., infrequent and inconsistent). Zones III and I, on the other hand, are “gray areas” where either acquisition or fossilization may occur, contingent upon the strength of individual learners’ memory capacities, for instance. Hence, the hypothesis predicts that fossilization (and acquisition) is selective, in both an inter- and an intra-learner sense, since combinations of L1 characteristics and L2 input conditions can vary from learner to learner, and, likewise, for the different domains and subsystems of an individual learner.

While this hypothesis has yet to be tested empirically, the fact that it singles out L2 input conditions as codeterminant of acquisition or fossilization naturally raises the question of whether input conditions can be improved, through instruction, for example. This and the more specific question of whether instruction can prevent fossilization, or, conversely, whether instruction can promote it, have been with us for a long time, and thus deserve a brief note here.

Can Instruction Constrain or Induce Fossilization?

It has long been held that the vast majority of L2 learners, in particular adults, are unable to acquire the target language to a reasonable extent, unless being subjected to formal instruction. Such conviction is fueled by several strands of research showing that instruction improves both the rate of acquisition and ultimate attainment; that older (instructed) learners have an initial developmental edge over younger (uninstructed) learners; that older learners do as well as younger learners vis-à-vis certain aspects of morphosyntactic acquisition; and that instruction eliminates learner errors, thereby improving accuracy and averting fossilization. All these findings serve to confer to instruction the status of an effective alternative, capable of compensating for older learners’ cognitive deficiencies, presumably incurred by neurobiological changes, L1 interference, and lack of a robust UG.

However, from very early on the SLA literature also reports that instruction can induce negative effects on learning. Even discussing the recent task-based language teaching, Skehan and Foster (2001, p. 205) caution that:

Unless it is appropriately handled, a task-based approach can over-emphasize the importance of just “getting the job done” at the expense of the central purpose of pedagogy: improving target language ability. As a consequence, it is more likely to have the effect of encouraging comfortable fossilization than that of promoting interlanguage (IL) development.

Instruction, then, can both stimulate and stall learning. Research has shown that instruction, on the one hand, may constrain fossilization such that, when fine-tuned, it can destabilize persistent and resistant interlanguage constructions, but, on the other hand, it can also breed fossilization (Han & Selinker, 1999).

Conclusion

The construct of fossilization is fundamental to understanding (adult) L2 acquisition. Although empirical research has firmly established its psychological and physical reality, the construct itself has nevertheless remained controversial to the present day, due primarily to epistemological differences in how learning and education are construed.

The history of SLA research shows, however, that the construct of fossilization has survived all prejudices against it, and, contra the expectations of some, has continued to function as a critical heuristic in SLA inquiries and a pillar for SLA theory construction, particularly as they relate to such central issues as ultimate attainment, the critical period,

the role of instruction, negative evidence, and the role of UG, to name a few. Any SLA theory claimed to be adequate must demonstrate a capacity for explaining and predicting both learning and nonlearning (Gass & Selinker, 2008). Understanding fossilization may also aid teachers' pedagogical practice. For example, being aware of which grammatical elements are prone to fossilization and understanding their different underpinnings can help improve teachers' sensitivity to the differential nature of grammatical elements, and help them set realistic expectations for the duration and outcome of teaching and learning. This should help maximize "the usability of the available resources to individual learners" (Han, 2004, p. 175), the most essential goal of L2 education.

Frame Analysis

YOUN-KYUNG KIM

The concept of “frame” is a useful tool to explicate how people interpret and at the same time construct their interactions coherently in specific interactional situations. To account for the exceedingly complex, but coherent nature of human interactions, the term “frame” is frequently used in the literatures in various disciplines including linguistics, sociology, anthropology, and so on. As Tannen (1993) contends, the notion of frame “provides a theoretical foundation for the discourse analysis of interaction” (p. 4). This entry describes the conception of frame by Bateson (1972), explains the notion of frame and its associated notions of keying and footing proposed by Goffman (1974, 1981), discusses various perspectives of frame or frame analysis used in different studies, and finally introduces some studies of discourse analysis that apply the concept of frame and its associated notions.

Bateson’s Conception of Frame

The concept of “frame” is traced back to Bateson (1972), who relates “frame” to “metacommunicative” level of abstraction of verbal communication. According to Bateson, human verbal communication operates at three levels of abstraction: first, the denotative level (i.e., referential level); second, the metalinguistic level (i.e., the subject of communication is language); and third, the metacommunicative level (i.e., communication regarding the intention and goal of an interaction). On the metacommunicative level, the interactants signal to each other the intention of the communication, so they can interpret what is really going on in the interaction and continue to construct the interaction coherently. Bateson states, “a frame is metacommunicative . . . [E]very metacommunicative message is or defines a psychological frame” (p. 188). In other words, frame is “a superordinate message about how the communication is intended” (Tannen, 1984, p. 23).

To illustrate frame, Bateson uses an example of monkeys that are *playing* by engaging themselves in interactive actions (e.g., biting) that are similar to but not the same as those of *fighting*, and he says “[T]his phenomenon, play, could only occur if the participant organisms were capable of some degree of metacommunication, i.e., of exchanging signals which would carry the message ‘this is play’” (p. 179). The frame of “this is play” allows the animals to interpret the potentially hostile move, such as biting, as not intended for enmity, which otherwise would be the interpretation at the denotative level of communication. Bateson also gives an example frame of “this is ritual” coming from peace-making ceremonies in the Andaman Islands, where “peace is concluded after each side has been given ceremonial freedom to strike the other” (p. 182).

Frame is a “psychological concept” (p. 186), but to explain this, Bateson uses a physical analogy of the picture frame: frame delimits a class or set of messages in such ways as a picture frame directs the viewer not to interpret the picture in the same way that she may use in interpreting the wallpaper outside the frame. In this sense, “frame defines, either explicitly or implicitly, the set of messages about which it communicates” (Bateson, 1972, p. 188). As Ensink and Sauer (2003) puts it, “the term ‘frame’ is, when applied to discourse, a metaphorical term . . . A frame thus gives structure to both an object itself and to the way the object is perceived” (p. 2).

“Frame,” “Keying,” and “Footing”

Bateson’s concept of “frame” gets its theoretical complexity in Goffman’s elaboration of “frame” and his notions of “keying” and “footing,” as presented in *Frame Analysis* (1974) and *Forms of Talk* (1981). According to Goffman (1974), a “frame” consists of “principles of organization which govern social events . . . and our subjective involvement in them” (pp. 10–11); that is, through frames, people organize experiences, and identify and define social interactions, in order to participate and maintain involvement in them. Frame refers to the fact that “discourse participants need a shared sense of the way in which the discourse is framed, i.e., an overall sense of the function of the discourse in the social situation” (Ensink & Sauer, 2003, p. 2).

Also, Goffman (1974) introduces a central concept in frame analysis, which is “the key” or “keying.” In an analogy of music, the key or keying refers to patterned change or *transformation* of the primary frame into another frame. Referring to Bateson’s example of animals playing, Goffman explains,

this play activity is closely patterned after something that already has a meaning in its own terms—in this case fighting, a well-known type of guided doing . . . In brief, there is a transcription or transposition—a transformation . . . of a strip of fighting behavior into a strip of play. (pp. 40–1)

Goffman refers to the process of transformation or transcription as “keying,” stating that

I refer here to the set of conventions by which a given activity, one already meaningful in terms of some primary framework, is transformed into something patterned on this activity but seen by the participants to be something quite else. (pp. 43–4)

Goffman’s later work, *Forms of Talk* (1981), introduces another nonseparable concept of frame—“footing.” “Footing” is defined as

the alignment we take up to ourselves and the others present as expressed in the way we manage the production or reception of an utterance. A change in our footing is another way of talking about a change in our frame for events. (Goffman, 1981, p. 128)

In other words, footing indicates how the participants view one another in relation to themselves in a specific frame. Therefore, footing can be viewed as participants’ social role relations and their perceptions of the role relations in frames, which often determine and shift frames. Goffman also says change in footing does not necessarily mean that the prior alignment is terminated but can be on hold to be reinstated. As an example, Goffman refers to a study of a pediatrician in a medical research/training facility, who continuously switches code back and forth, “addressing her youthful patients in ‘motherese,’ now sustaining a conversation-like exchange with the mother, now turning to the video camera to provide her training audience with a running account couched in the register of medical reporting” (p. 156). Also, Goffman maintains that footing or change in footing is commonly “language linked” (e.g., speaker’s code switching, pitch, volume, stress, and tonal quality), and provides a rationale for linguistic analysis of footing, or frame in general, by saying, “linguistics provides us with the cues and markers through which such footing become manifest, helping us to find our way to a structural basis for analyzing them” (p. 157).

Various Perspectives of Frame Analysis: Interactive Frame and Cognitive/Knowledge Frame

Admittedly, however, the concept of “frame” has been used in various, but complex, ways in different disciplines, such as linguistics, anthropology, sociology, artificial intelligence, ethnography of speaking, and interactional sociolinguistics (Tannen, 1993; Tannen & Wallat, 1993; Lee, 1997; Ensink & Sauer, 2003). For example, a type of frame is referred to, when Gumperz (1982) describes “speech activity” as a “means through which social knowledge is stored in the form of constraints on action and on possible *interpretation* [emphasis added],” in which “a set of social relationships [is] enacted about a set of schemata in relation to some communicative goals” (p. 166). A similar concept to frame is also involved, when Gumperz refers to interactive process as “contextualization,” which is defined as “the identification of specific conversational exchanges as representative of socio-culturally familiar activities” (p. 162). Along this line, “contextualization cues” are defined as linguistic features signaling the on-going speech activity and contextual presuppositions in it (Gumperz, 1982, p. 131). The concept of contextualization cues relates to above-mentioned Goffman’s (1981) remarks on how footing or changes in footing are “language linked” (p. 157). Connecting Gumperz’s work with Goffman’s concepts of frame and footing, Schiffrin (1994), in the discipline called *interactional sociolinguistics*, defines that frame—as interactional order underlying social situations and encounters—provides and constrains *contextual presuppositions* for accurate interpretations or *situated inferences* of speakers’ meanings. Schiffrin views contextualization cues not only as signals for changes in footing, and thereby frames, but also as “framing devices”; that is, contextualization cues indicate the frame in which an utterance should be interpreted (p. 103).

On the other hand, according to Tannen (1993), the discussion of frame rests on the notion of “expectation,” which is basically formed by one’s past experience of the world. Specifically, Tannen (1993) uses the term, “frame,” to refer to “structures of expectation,” and emphasizes the role of knowledge structure in shaping expectation and framing interactions, stating that “on the basis of *one’s experience of the world* in a given culture, one *organizes knowledge* about the world and *uses this knowledge* to predict interpretations and relationships regarding new information, events, and experiences [emphasis added]” (p. 16). Tannen contends that the concept of “structures of expectation” underlies the discussion of “frame,” “schema” used by Bartlett, and “script” used by Schank and Abelson (all cited in Tannen, 1993, pp. 15–18). By saying this, she places all of these terms or concepts on the similar conceptual dimension, focusing on *cognitive* aspects of frame. That is, Tannen (1993) uses frame as *expectation* and *knowledge structure* (cognitive/knowledge frame), while Bateson and Goffman use frame as *interpretational* and *inferential* dimension (interactive frame).

To show that the notion of frame can be understood as *structures of expectation* based on past experience, Tannen (1993) has investigated oral narratives in which young women retell events in a film to other women under an experimental condition. According to the results, while various overlapping levels of frames operate (e.g., a frame of storytelling, a frame about the content of the story in the film, and others) within the frame of oral narratives in the context of an experiment, the speakers’ language use reveals the imposition of their expectations on the content of the film, and the evidence of the speaker’s expectations is showed and categorized in 16 types of their language use—omission, repetition, false starts, backtrack, hedges, negatives, contrastive connectives, modals, inexact statements, generalization, inference, evaluative language, interpretation, moral judgment, incorrect statements, and addition. In a slightly different vein, Lee (1997) uses a concept of a *cognitive frame* from a perspective of cognitive grammar, especially in association with “profiling”

by Langacker and “radial category” by Lakoff (all cited in Lee, 1997, p. 339). In his discourse analysis of family arguments, in which competing frames held by different family members conflict and cause disagreements, Lee contends that *interactional frames* (i.e., the mode of interaction) is related to *cognitive frames* by shedding light on interpreting the specific utterances or words.

The interaction between *cognitive frame* and *interactive frame* is also recognized in the study of Tannen and Wallat (1993). Acknowledging various uses and concepts of frame as discussed above, Tannen and Wallat (1993) describe these uses of frame in terms of *interactive* and *cognitive* dimensions, and categorize them into two types: “interactive frames of interpretation” and “knowledge schemas” (pp. 59–61). “Interactive frames of interpretation” is Bateson’s and Goffman’s notion of frame (interactive frame); “knowledge schemas” are similar to Tannen’s concept of frame (cognitive/knowledge frame), defined as “participants’ expectations about people, objects, events and settings in the world, and ways to interact” (p. 60), which is dynamic by being continually revised according to the participants’ experiences. According to Tannen and Wallat, both the *interactive frame* and *knowledge schema* interact and affect the participant’s comprehension of specific utterances. Along this line of thoughts, in their study of pediatrician investigating a child in the presence of the mother, Tannen and Wallat show how mismatch in knowledge schemas (cognitive/knowledge frames) between the doctor and mother can trigger frame changes among “examination” frame, “consultation” frame, and “reporting” frame (interactive frames).

These two dimensions of frame—interactive frame and cognitive/knowledge frame—are also recognized by Ensink and Sauer (2003), but they argue for another separate category or type of frame—*footing* and *keying* (changes in frame) (Goffman, 1974, 1981)—to be added to this categorization. Especially, Ensink (2003) emphasizes that Goffman’s (1974) concepts of the “key” or “keying” (i.e., patterned transformation of a frame to another one) should be elaborated and regarded as a separate category. Ensink argues that different frames (such as “fighting” and “playing”) are not on the symmetrical level. For example, we can say “monkeys play that they are fighting,” but we cannot say “monkeys fight that they are playing.” That is, “fighting” is a frame in its own right, but cannot embed another frame; however, the frame of “playing” can embed another one. “Fighting” is a primary frame, but “playing” is a transformational frame containing or embedding the primary frame within it. Ensink contends that the interactive frame is subcategorized into “proper interactional frames,” which is a primary frame its own right (e.g., monkeys fighting in Bateson’s example), and “transformational frames” in which proper interactional frames are modified (e.g., monkeys playing in Bateson’s example) (p. 67). As Ensink maintains, the transformational frames are the “key” in Goffman’s notion (1974)—patterned change(s) of the primary frame into another frame. If the transformations of frames are not recognized by participants, fundamental communicative misunderstanding occurs. Participants embed or de-embed frames to restore intended interpretation, and thereby, transformational frames influence interpretation. Basically, Ensink (2003) argues that since proper interactive frame (i.e., primary frame in Goffman’s term) and his transformational frame (i.e., the key or keying in Goffman’s term) are in asymmetrical relationship, the transformational frame should be recognized as a separate type in frame and frame analysis.

Studies of Frame Analysis

Other studies used frame analysis to analyze interactions, some of which are introduced here. Some studies show how all communicators, including psychotic patients and children, use framing to organize their discourses and manage divergent interactional tasks. In the frame of a psychiatric interview, Ribeiro (1993) shows how the seemingly incoherent

psychotic discourse of a 61-year-old thought-disorder patient actually achieves coherence while shifting frames coherently (i.e., psychiatric interview frame and the frame of psychotic crisis) and talking in different roles. Hoyle (1993) discusses how three eight- and nine-year-old boys manage footing and frame shifts in their sportscasting play by signaling these shifts through the ways they use names and pronouns.

A nonseparable concept of frame—"footing" (Goffman, 1981)—has been investigated in various social contexts. For example, Straehle (1993) shows how teasing among three conversationalists plays a role in negotiating their footing among themselves. That is, the three conversationalists do not engage in the frame of teasing in the same way; the meta-message which frames their unique teasing relationship is their relative closeness and types of relationships among them. Schiffrin (1993) examines the frame of sociolinguistic interviews, in which an interactional move, "speaking for another," negotiates footing among the informants by providing them with opportunities to shift styles and identities. Kendall (cited in Kendall & Tannen, 2003, p. 559) uses notions of frame and footing in examining family dinner talk in terms of how parents create gendered identities. In this study, the mother accomplishes multiple tasks in several interactional frames, whereas the father participates minimally, and maintains only one frame at a time in more symmetrical footing with the daughters.

More recent studies examined another important concept of frame analysis, which is the "key" (Goffman, 1974). Jacobs (2003) analyzes the frame of press releases, especially focusing on the concept of the "key." He sees the frame of press releases as keys, and since the reporter expects and calculates in advance the role of the report, he calls this calculation "pre-keying." He regards pre-keying in press releases as indication of increased influence of the media in social life. Cowper (2003) applies the concept of frame to her analysis of real and satirized political interviews to show how the primary frame of normal political interview is transformed or "keyed" to the satire, within which the behavior is patterned after those in the primary frame.

Some studies use frame analysis in the studies of interactions involving non-native speakers of English or different cultural groups, as well as native speakers of English. Watanabe (1993) investigates cultural differences in framing a speech event, that is, group discussion, in a university setting by comparing four American group discussions with three Japanese group discussions. She contends that in the same kind of speech event or frame, participants from different cultures may interact differently due to their differences in framing interactions. Kim (2009) applies frame analysis, in conjunction with contextualization cues (Gumperz, 1982), to the discourse analysis of university writing center interactions involving native and non-native speakers of English. This study shows how different layers of frames held by tutors and students conflict and at the same time intertwine within the frame of writing center conference, as evidenced in the volubility (turn length and distribution) and questions (question types and frequencies) of the participants.

Conclusion

Since the conception of "frame" for analyzing interactions in Bateson (1972), various scholars in different disciplines have refined and elaborated on this concept and have used it in various dimensions or perspectives in their analyses of interactions—that is, frame analysis (e.g., Goffman, 1974, 1981; Tannen, 1993). Frame is basically assumed to be underlying a coherent interaction, and research in frame analysis tends to use the concept in conjunction with other notions or methods of discourse analysis. Some recent studies attempt to add theoretical elaboration and complexity to the notion of frame and frame analysis, more firmly establishing frame analysis as an independent research area (e.g., Ensink, 2003).

Francis, Nelson

CHARLES F. MEYER

Winthrop Nelson Francis (also known as Nelson Francis) was a renowned historian of the English language, dialectologist, and corpus linguist. He is best known as cocreator (with Henry Kučera) of the Standard Sample of Present-Day American English (or Brown Corpus, as it is commonly called), the first computer corpus ever created. The Brown Corpus was a major accomplishment: not only did it provide the linguistic community with the first machine-readable electronic database of edited written American English, but it opened the era of corpus linguistics and provided a model for corpus compilation and analysis that extends to the present.

Nelson Francis was born in Philadelphia, PA in 1910 and died at the age of 91 in 2002 (much of the biographical information in this section is taken from Kučera, 2002). Francis's initial exposure to language study resulted from the classical education he received in Latin, Greek, and French both in primary school and as an undergraduate at Harvard. Francis's interest in language grew while he attended graduate school at the University of Pennsylvania, where he wrote a doctoral dissertation that was a translation of the late 13th-century French text *La Somme le Roi* by Lorens d'Orléans ('*The Book of Vices and Virtues*'), published in 1942. Following receipt of his doctorate, he received a teaching position at Franklin and Marshall College in Lancaster, PA, where he taught many courses, including Old English and the history of the English language, from 1937 to 1962. During this period, the American structuralist movement dominated linguistic thinking in the United States, an influence that can be seen in one of Francis's early books, *The Structure of American English* (1958). This textbook brought the perspective of structuralists such as Charles Fries to a description of phonetics, phonology, morphology, syntax, and dialects, and it also reflected a strong commitment by Francis to teacher education.

In 1962, Francis became a professor of linguistics and English at Brown University in Providence, Rhode Island. Shortly after assuming this position (1963), a textbook he had written, *The History of English*, appeared, and he began a lengthy collaboration with Henry Kučera, also a professor of linguistics at Brown. The two worked together to create the Brown Corpus, a corpus of edited written American English consisting of different types of written texts published in 1961. At this time, the generative movement was gaining influence in the United States at the expense of key structuralist tenets, such as the need to base linguistic analyses on empirical data. Thus, the Brown Corpus was not warmly received by many members of the mainstream linguistic community. Francis (1992, p. 28) comments that a leading generative grammarian of the time (unnamed in his commentary) characterized the creation of the Brown Corpus as "a useless and foolhardy enterprise" because speaker intuitions (not a corpus) were "the only legitimate source of grammatical knowledge about a language."

But while many linguists may have felt that a corpus was merely a repository for the study of "old ideas," the Brown Corpus was actually a novel undertaking at the time. Pre-electronic corpora had existed prior to the Brown Corpus. For instance, Otto Jespersen based the seven-volume *A Modern English Grammar on Historical Principles* (1909–49) on a large collection of printed texts. But the Brown Corpus was the first corpus to be distributed in a computerized format, and to employ a rigorous methodology for text collection that is still relevant and widely employed.

To plan the overall design of the corpus, Francis and Kučera held a conference at Brown University in 1963 that was attended by John B. Carroll, Philip B. Gove, Patricia O'Connor, and Randolph Quirk. After considerable discussion, conference attendees decided that the corpus would be 1 million words in length, and contain 2,000 word excerpts taken from texts published in 1961 that represented the following genres of edited written American English (Francis & Kučera, 1979):

Informative Prose

press: reportage, editorials, and reviews
 religion
 skills and hobbies
 popular lore
belles lettres, biography, memoirs, and so forth
 miscellaneous (e.g., government documents, foundation reports)
 learned

Imaginative Prose

general fiction
 mystery and detective fiction
 science fiction
 adventure and western fiction
 romance and love story
 humor

The size and composition of the corpus was based on a number of methodological assumptions that emerged at the conference. First, to adequately sample the range of variation in written English, differing types of informative and imaginative prose needed to be selected. For instance, because a newspaper editorial is different from a scientific article, examples of both kinds of writing needed to be included so that the different kinds of English inherent in each were represented in the corpus. The same kind of thinking guided the choice of the other categories too. Of course, not every type of written English was included in the corpus. Verse was excluded because it is a very specialized form of imaginative language.

While breadth of coverage influenced the choice of genres to be included in the corpus, other considerations (some primarily logistical) affected the decision to restrict the length of the corpus to one million words and to include text excerpts (rather than complete texts). At the time that the corpus was created, optical scanning did not exist. As a result, the entire corpus had to be keyed in by hand, requiring that the overall length of the corpus be kept to a reasonable length (see the entry for Henry Kučera for more information on the computational aspects of the corpus). To insure that as many different texts and writers as possible were included, it was decided that ca. 2,000 word excerpts from a given text be included. The selection of texts and excerpts necessitated very specific selection criteria. Potential texts in a given category were randomly selected, as was the specific page in a text from which the 2,000-word excerpt would begin to be collected. An encoding scheme also had to be developed. For instance, the symbol **. was used to mark a period ending an abbreviation (as in etc**.) from one ending a sentence. Even though the issues that Francis and Kučera had to address when creating the Brown Corpus have long been resolved, it is important to realize just how seminal work on the Brown Corpus has been to the development of subsequent corpora.

The first version of the corpus was released in 1964 (five additional revised versions have been released since then). In 1967, Kučera, Francis, and Carroll published a book,

Computational Analysis of Present-Day American English, that provided word frequency information based on the Brown Corpus. Although word frequency lists had been created previously, this was the first such list that was based on a carefully collected group of texts and that contained frequency information not just for the entire corpus but for the individual genres of the corpus. One problem with the lists contained in this book is that they were based solely on the orthographic forms occurring in the corpus. Thus, as Burchfield (1985, p. 66) notes, "Homonyms like *bear* (verb) and *bear* (animal) were lumped together." To rectify this deficiency, in 1982, Francis and Kučera published a second book, *Frequency Analysis of English Usage: Lexicon and Grammar*, containing an updated word frequency list based on a lexically tagged version of the Brown Corpus. In a tagged corpus, each word is assigned a part of speech label. Thus, in *The bear is hungry*, *bear* would be tagged as a noun, and in *You bear full responsibility*, it would be tagged as a verb (further information on the set of tags for the corpus is given in the entry for Henry Kučera). Obviously, frequency lists based on a tagged corpus provide more accurate information on the distributions of words. Still, they cannot distinguish words having the same part of speech but different meanings. For instance, *bank* is a noun in both *I withdrew money from the bank* and *We stood by the bank of the river*, but has a completely different meaning in each sentence.

Following the creation of the Brown Corpus, Francis continued work in both corpus linguistics and other areas of linguistics. In 1983, he wrote an introductory text on dialectology entitled *Dialectology: An Introduction*. At the Nobel Symposium in Stockholm in 1991, he delivered a paper, "Language Corpora BC" (later published in Francis, 1992), that described pre-electronic corpora, such as the print-based corpora used as the basis for citations in Samuel Johnson's 1755 *A Dictionary of the English Language* and the *Oxford English Dictionary*. The "BC" (Before Computers) in the title was intended to stress the notion that while computerized collections of texts are a very recent phenomenon, grammarians have for centuries been analyzing texts by hand for purposes of linguistic analysis.

In 1995, both Francis and Kučera were honored at the 16th annual meeting of the International Computer Archive and Modern and Medieval English (ICAME) held in Toronto (see also the ICAME Web site at <http://icame.uib.no/>). A special session was convened at which various speakers described the important contributions that they had made to the development of the field of corpus linguistics. Speakers at the session noted the influence the Brown Corpus had had on subsequent corpora (a summary of the responses was published in the *ICAME Journal* in 1996). For instance, several corpora replicated Brown but with comparable written texts from other national varieties of English: the London–Oslo–Bergen (LOB) Corpus (British English), the Wellington Corpus (New Zealand English), and the Kolhapur Corpus (Indian English). The Freiburg–Brown Corpus of American English (FROWN) and the Freiburg–LOB Corpus of British English (FLOB) were similar to Brown and LOB but contained written texts published in the early 1990s, thus enabling historical comparisons. The International Corpus of English (ICE), which contains components representing the various national varieties of English (such as American, British, Irish, East African, and New Zealand English), has a similar design to Brown. Each regional team is creating a 1 million-word corpus divided into 2,000 word excerpts. However, spoken as well as written English is included.

Although more recent corpora have become larger and more diverse in composition, they all owe their existence to the important groundwork that Francis and Kučera laid in creating the Brown Corpus.

French, Peter

JONAS LINDH

Peter French (1953–) is honorary professor in the Department of Language and Linguistic Science at the University of York. He is probably the world's most experienced speech scientist in respect of forensic casework. He has been consulted as an expert witness in more than 5,000 cases arising from countries throughout the world and has appeared in court on over 200 occasions. The cases in which he has been consulted have been heard before courts of all levels, including International Commissions of Enquiry and the International War Crimes Tribunal. With regard to the latter court, he provided evidence for the genocide trial of the President of the former Yugoslavia, *United Nations v. Slobodan Milošević* (http://www.icty.org/case/slobodan_milosevic/4). In the United Kingdom his involvement in the case *R v. Ingram, C., Ingram, D., and Whittock, T.*—the so-called “‘Who Wants to Be a Millionaire?’ Fraud Trial”—received wide media attention (French & Harrison, 2004).

After reading linguistics and phonetics at the University of Manchester, Professor French went on to complete a PhD thesis on conversation analysis at Bristol University in 1982. Thereafter, his early research interests and publications were broadly based and eclectic, integrating methods, findings, and insights from the disciplines of child language development, traditional dialectology, conversation analysis, and phonetics. With regard to phonetics and conversation analysis, his study of the prosodic features of interruptions, conducted with John Local (French & Local, 1983), was the initial step leading to the now firmly established field of study, the phonetics of talk-in-interaction (sometimes referred to as “interactional phonetics”). He held academic positions as phonetic fieldworker, research assistant, lecturer, and then senior lecturer before the well-known dialectologist, the late Stanley Ellis (<http://www.leeds.ac.uk/secretariat/obituaries/2009/obituary6698.html>), persuaded him to become involved in forensic phonetic casework in the mid-1980s. After trying to juggle the often-conflicting demands of an academic position with those of a growing forensic practice, the latter held sway and he left his full-time academic post in 1989.

In that same year French organized the first Annual Conference on Forensic Phonetics, which was held at St. John's College, York (now York St. John University). A further conference was held the following year at the same location before the founding of the professional organization, the International Association for Forensic Phonetics (IAFP) in 1991. Professor French was elected as the Association's first chairman and subsequently reelected four times. In 2006, at the end of his fifth period of office, he was elected president of what had by then become the International Association for Forensic Phonetics and Acoustics (IAFPA) (www.iafpa.net), a position that he still holds. He is also a member of the International Phonetic Association, a registered professional member of the British Association of Academic Phoneticians, a fellow and UK secretary of the International Society for Phonetic Sciences, a fellow of the Royal Society of Arts, a fellow of the Royal Society of Medicine, and a fellow of the Institute of Acoustics.

In 1990, he coauthored with John Baldwin one of the earliest full-length overview texts on forensic phonetics (Baldwin & French, 1990). Since then he has periodically produced updated conspectus articles, which have been published in a variety of sources (French,

1994, 2007; Foulkes & French, 2001, 2011; French & Harrison, 2006). His major continuing contribution to the research community has been to reflect the problematic connection between research and practical casework. Case studies have been published mainly in *The International Journal of Speech Language and the Law* (formerly *Forensic Linguistics*) (French, 1998; French & Harrison, 2004; French, Harrison, & Windsor Lewis, 2006), of which he was a founding editor and presently coedits.

In recent years, he and members of his company, JP French Associates Forensic Speech and Audio Laboratory, have worked in close collaboration with colleagues from the Universities of York and Cambridge, in particular with Professors Paul Foulkes and Francis Nolan and Dr. Dominic Watt. Their contributions to the field of forensic speaker comparison have been in three key areas. First, they have sought to emphasize the importance of gathering data on inter- and intra-speaker variation in respect of potentially speaker-discriminating phonetic and acoustic variables. Second, they have pioneered and continue to undertake research on the reliability of automatic speaker recognition systems when operating with real UK forensic recordings, and on the integration of such systems into forensic speaker comparison test batteries. Third, and perhaps most prominent, has been Professor French's work on a logically coherent framework for expressing conclusions in forensic speaker comparison cases (French & Harrison, 2007). Whilst finding almost unanimous favor in the UK forensic speech community and being adopted by nearly all UK practitioners, the framework was opposed by some proponents of the likelihood-ratio (LR) framework for the interpretation of evidence in forensic speaker comparison cases (Rose & Morrison, 2009). The major argument centers around how one can best present and evaluate the conclusions in speaker comparison cases logically, while avoiding expressions which result from misunderstanding the concept of conditional probability. Within the numerical LR approach, the evaluation of results involves one calculating the ratio of the likelihood of finding a combination of correspondences/differences between the known recording of the suspect and the criminal recording on the proposition that they are of the same speaker, over the likelihood of finding the same evidence on the proposition that they reflect different speakers. From French's perspective, we lack the demographic data to make this numerical calculation and he points to difficulties in defining relevant reference populations. Instead, he has argued, we should express conclusions verbally, potentially in two steps. The first step involves presenting a decision on whether the speech in the known and criminal samples is *consistent* with having been produced by the same person. If there is a positive outcome to the consistency decision, one progresses to the second step, which involves an impressionistic, experience-based assessment of the degree to which the features common to the samples are unusual or *distinctive*. The counterarguments put forward by Rose and Morrison (2009) are, *inter alia*, that this approach "considers speech features as discrete"; its authors "propose distinctiveness statements while acknowledging the absence of information upon which to base them" and that "the absence of a way of relating the consistency and distinctiveness assessments does not help the trier-of-fact to interpret them." The debate on these issues has been extended by a further rejoinder from French, Nolan, Foulkes, Harrison, and McDougall (2010) to the Rose and Morrison critique. Both positions, however, emphasize the importance of changing the concept of identification to comparison, as the former implies knowledge of a hypothesis given the evidence, which would be a logical flaw.

Aside from Professor French's own research, one of his greatest contributions to the field of forensic speech science has been to create opportunities for others to conduct research and undertake casework in that area. He has done this by working stalwartly over the years to bring the subject into the public arena for open discussion, and, in the early days, by encouraging those who harbored skepticism toward forensic speaker comparison work to become involved in the activities of the IAFPA.

More recently, Professor French has worked with Paul Foulkes on planning and developing the world's first MSc degree in Forensic Speech Science in the Department of Language and Linguistic Science at the University of York. French continues to lecture on the degree and supervises a number of PhD students in the department. He has also provided in-house training to technical and scientific staff of the Metropolitan Police in London and to the FBI and United States Secret Service in Washington DC.

JP French Associates has grown in size and stature over the years and its staff continue to initiate research and methodological developments. We can expect the forensic speech science community internationally to benefit from and grow alongside these advances, thanks to the work of Peter French.

Functional Approaches to Translation

CHRISTIANE NORD

Translation studies is still quite a young discipline. It started as a branch of applied linguistics in the 1960s, partly pushed by a growing interest in machine translation (see Oettinger, 1960), partly under the influence of Bible translation (see Nida & Taber, 1969). The need for a theoretical groundwork for translator and interpreter training, which became particularly pressing in Germany and other European countries during the 1970s, triggered several profession-oriented tendencies in translation research, among them the investigation of the translation process by thinking-aloud protocols (TAPs; Lörscher, 1991) and functionalist approaches (see Nord, 1997), to name but two.

Historical Background

A functional perspective on translation is not an invention of the 20th century. From the beginning, translators like Cicero (106–43 BCE), Jerome (348–420), Martin Luther (1483–1546), or the German theologian and philosopher Friedrich Schleiermacher (1768–1834) reflected on their translation activity and found themselves confronted with a fundamental dilemma: They could either translate literally or even word for word, keeping as close to the source text as possible, which often resulted in a text that was hard to read or even incomprehensible for the target audience, or they could translate the sense instead of the words, as St. Jerome put it in his *Letter to Pammachius*, producing a text that was acceptable and easy to read for the target audience but—depending on the linguistic and cultural distance between source and target—might require a large amount of rephrasing and restructuring and give rise to misinterpretations. The motive for choosing one strategy or the other could be seen, for example, in the type of text that had to be translated (e.g., holy vs. profane in the case of Jerome, literary vs. pragmatic in the case of Schleiermacher), in the translation norms of the target culture (e.g., foreignizing vs. domesticating, see Venuti, 1995), or in the communicative purpose that had to be achieved by the target text (e.g., dynamic equivalence, Nida, 1964). But with the advent of linguistics-based approaches to translation, these viewpoints, which had their origin in the practice rather than in the theory of translation, were replaced by a strictly linguistic perspective searching for equivalence relations between language systems. Even Nida converted to a Chomskyan model of the translation process, in which source-text surface elements (grammar, meaning, connotations) are analyzed as linguistic kernel or near-kernel structures that can be transferred to the target language and restructured to form target-language surface elements (Nida, 1976, p. 75). This model, with equivalence mainly on word and phrase level as the key concept, dominated the first phases of what was to become translation studies.

In the early 1970s, the German scholar Katharina Reiss, still firmly drawing on an equivalence-based concept of translation, developed a translation-oriented text typology intended to serve as a guideline to translators (Reiss, 2000), in which she postulated that an analysis of the type represented by the source text would set the standards for the production of the target text, because the latter had to be a representation of the same text type as the former. But drawing on her own experience in translation practice, Reiss recognized that there were certain limitations to this iron rule of equivalence, of which

the “functional” category is of particular importance. This category includes the specific function of a translation in contrast with that of the original (e.g., in résumé translations, translations for study purposes, Bible translation, adaptations of literary works for the stage), and the possibility that the target text might address a different kind of audience than the source text (as in translations of adult literature for children or popularizations of specialized texts for a lay audience). It is this functional category in her model that is considered today to be the starting point of functionalism in translation theory, although it was regarded as an exception to the rule of equivalence by the author herself, who never really turned away from an equivalence-based approach.

It was Hans J. Vermeer, whose teacher at the School for Translation and Interpreting of Heidelberg University was, in fact, Katharina Reiss, who broke with linguistic translation theory and turned Reiss’s model upside down. In the framework of his theory, which he named *skopos* theory (*skopos* being the Greek word for “purpose, aim”), change of audience and function(s) is the rule, whereas establishing (some kind of) “equivalence” may be one among various possible purposes.

Drawing on action theory (von Wright, 1968), Vermeer defines translation as a particular type of action which, like every human activity, is geared toward a purpose. Human actions take place in situations, situations are embedded in cultures, and hence any evaluation of a particular situation, of its verbalized and nonverbalized elements, depends on the status it has in a particular culture system (Vermeer, 1978). In this situation, a text is used to transmit a message from a sender to a receiver, and the way this message is “wrapped up” by verbal and nonverbal means depends on the specific norms and conventions of behavior regarded as acceptable in a particular culture.

This model is based on a new concept of what a text is. Vermeer considers a text to be an “offer of information” (Reiss & Vermeer, 1984, pp. 73–6). Faced with this offer, any receivers (among them, the translator) choose the items they regard as interesting, useful, or adequate to the desired purposes. In translation, the chosen informational items are then transferred to the target culture using the presentation the translator believes appropriate for the given purpose. In Vermeer’s terminology, a translated text or *translatum* is thus a new offer of information in the target culture about some information offered in the source culture and language.

Basic Concepts and Ideas of *Skopos* Theory

According to *skopos* theory, the prime principle determining any translation process is the purpose of the overall translational action. This fits in with intentionality being part of the very definition of any *action*. Apart from the term *skopos*, Vermeer uses the related words *aim*, *purpose*, *intention*, and *function*. In order to avoid confusion, I have proposed a basic distinction between *intention* and *function* (Nord, 2005b, p. 53). *Intention* is seen from the viewpoint of the sender, who wants to achieve a certain purpose with the text, but it is the receivers who, depending on their own communicative needs and expectations, attribute a particular *function* to it. In an ideal situation, the sender’s intention will find its aim, in which case intention and function would be analogous or even identical. But since function is not a quality inherent in a text, it cannot be “changed” or “preserved” in the translation process. Rather, translational, that is, mediated, communication has to cross a language-and-culture barrier, and what was “sent” with a particular intention on one side of it, may be “received” in a different function on the other. It thus seems quite plausible that the larger the cultural (and usually also temporal, geographical, etc.) distance, the less probable it becomes that intention and function are identical, and receivers sometimes assign certain functions to a text which the sender never dreamed of.

If it is no longer the source text that sets the standards for translation, as assumed by equivalence-based theory, we have to ask who decides what the standards should be. The answer is fairly obvious. Translation is usually done by assignment. A client needs a translation for a particular purpose and commissions a translator. In an ideal case, they would provide as much information as possible about the purpose, the audience, time, place, and medium of the intended communication, and the function the text is intended to fulfill. This information would constitute a *translation brief*. The brief does not tell the translator *how* to go about the translating job, what translation strategy to use. These decisions depend on the translator's responsibility and competence. Since reality is usually far from ideal, translators often have to infer the necessary information from the translational situation or ask the client to provide it. But it is obvious that if the purpose is clear it is much easier to produce a *translatum* which fits this purpose.

In such a framework, equivalence as a once-and-for-all standard for translation quality is obsolete. Instead, we would speak of *adequacy*. Adequacy is a relative concept: A target text is (or is not) adequate to the requirements of the translation brief. If the brief requires equivalence, equivalence would be adequate. If the brief requires some other relationship between source and target text, an equivalent translation would be inadequate.

One of the great merits of *skopos* theory is to have brought culture to the fore. For Vermeer, a culture is "the entire setting of norms and conventions an individual as a member of his society must know in order to be 'like everybody'—or to be able to be different from everybody" (Vermeer, 1987, p. 28). Cultural features have been termed "culturemes." A cultureme is a social phenomenon of culture X that is regarded as relevant by the members of this culture and, when compared with a corresponding social phenomenon in culture Y, is found to be specific to culture X. "Corresponding" here means that the two phenomena are comparable under certain definable conditions (Vermeer & Witte, 1990, p. 137). For example, they may be different in form but similar in function (as in taking a train vs. going by car vs. riding a bicycle to reach your workplace) or vice versa (e.g., *to have coffee* in England in the morning vs. *tomar un café* in Spain after dinner vs. *Kaffee trinken* in Germany in the afternoon). Translating means comparing cultures. Translators interpret source-culture phenomena in the light of their own culture-specific knowledge of that culture, from either the inside or the outside, depending on whether the translation is from or into the translator's native language and culture. A foreign culture can only be perceived by means of comparison with our own culture. If every action is to be seen in the context of a specific culture, this applies to translation as well. We may thus assume there are various culture-specific concepts of what constitutes translation or a translational action.

Applications to Translator Training

Right from the outset, *skopos* theory had a considerable impact on translator training, first in Germany and, after some of the early works by Vermeer and his followers had been published in English, Spanish, or Portuguese, also in other parts of the world. University-based translator training has quite a long tradition in Germany, but teachers, who had usually been trained in foreign-language acquisition, linguistics, or literary studies themselves, followed language-oriented, equivalence-based models in their translation classes, which did not really prepare students for the profession. Therefore, *skopos* theory was welcomed particularly by translator trainers, who had been looking for a practice-oriented, applicable theoretical groundwork and methodology for some time. With a view to professional translation, it seemed to make sense to use the intended function(s) as a guideline for both novices and professional translators. In their book *Strategie der Übersetzung*

(“Strategy of Translation”) of 1982, Hönig and Kussmaul showed that “adequacy” to a given aim, which is formulated in a *translation brief* (in German, *Übersetzungsauftrag*) is a much more plausible standard for translation quality than “equivalence,” particularly because equivalence has not really been defined in a satisfactory way so far, and “functional equivalence,” which Nida postulated for translating the Bible for missionary purposes, is not always possible, let alone desired. The so-called “functionalists” of the second generation adapted *skopos* theory to teaching methodology (e.g., Kussmaul, 1995), translation quality assessment (e.g., Kupsch-Losereit, 1985), translation-oriented text analysis and translation typology (e.g., Nord, 2005b), claiming that it was useful for the translation not only of advertising or technical texts (e.g., Göpferich, 1995; Schmitt, 1999) but also of opera libretti (e.g., Kaindl, 1995), literary works (e.g., Nord, 1997, pp. 80–103) or even biblical texts (e.g., Nord, 2005a). Although Vermeer had claimed that his model was a general theory which applies to both translating and interpreting, most of his followers focused on translating in the written mode. However, the Austrian scholar and practicing conference interpreter Franz Pöchhacker has shown in a well-documented study (Pöchhacker, 1995) that functionalism can also be fruitfully applied to conference and other forms of interpreting. In order to set a limitation to the otherwise unlimited range of possible translation purposes for one specific text, and to account for culture-specific concepts of translation, particularly with regard to the translation of sensitive or ideological texts, Nord (1997, pp. 123–8) introduced the ethical category of loyalty into functionalism. Loyalty is the responsibility translators, as experts in two languages and cultures, have toward their partners in translational interactions. It is not a category referring to a static relationship between texts, as equivalence or fidelity, but an interpersonal category referring to a social relationship between people.

Conclusions

After having been confined to the German-language area for quite some time, *skopos* theory and functionalism are now accepted worldwide, both for teaching and research. It is particularly useful in multilingual and multicultural societies, like South Africa, because it is:

- a pragmatic model, accounting for the situational conditions of communicative interaction, and for the needs and expectations of the addressees or receivers of the target text and even making them the most important yardstick of translational decisions;
- culture-oriented, giving consideration to the culture-specific forms of verbal and non-verbal behavior involved in translation;
- consistent, because it is able to establish a coherent theoretical and methodological framework which can serve as a guideline for an intersubjective justification of the translator’s decisions in any type or form of translation assignment, permitting any translation procedures that would lead to a functional target text, without infringing on the translator’s loyalty obligations;
- practical, including all the forms of transcultural communicative mediation needed in professional translation practice;
- comprehensive, since it can be applied to any translation process, including those where some kind of (functional, formal, informational, etc.) equivalence is required.

Functionalism is not, as is sometimes criticized, a theory of adaptation. Although the general focus is on the audience and its needs and expectations, these may, in certain cases, include even a literal or word-for-word translation if the commission requires “to translate

literally in order to show the structural particularities of the source language" as in inter-linear translations for linguistic purposes (see Vermeer, 1989, p. 100).

Moreover, it is an expert model in the sense that it attributes to translators the prestige of being experts in the field, competent to make purpose-adequate decisions with full loyalty toward their partners. In this sense, functionalism is a chance for the development of a fully-fledged profession of translation studies as an important scholarly discipline.

Functional Grammar

DANIEL GARCÍA VELASCO

Functional Grammar

The theory of *Functional Grammar* (FG) was originally developed by the late Simon C. Dik and his associates at the University of Amsterdam, the Netherlands. It takes a functional approach to the study of language which is reflected in (a) the description of language as an instrument of social interaction whose main function is the establishment of interhuman communication; (b) the requirement that language structure be studied within the framework of the rules, principles, and strategies which govern its communicative use and (c) the integration of functional relations in the organization of the theory.

FG also aims at developing a formal system of representation in which linguistic analyses can be stated in an explicit way. This commitment to explicitness and rigor in grammar construction is also reflected in Dik's self-imposed standards of adequacy, clearly reminiscent of those proposed by Noam Chomsky for generative grammars. Standards of adequacy are defined as requirements which grammar models must meet if they are to provide a satisfactory account of natural language. Dik proposes the following (Dik, 1997, p. 13):

- *Pragmatic adequacy*: FG should state the properties of linguistic expressions in such a way that it accounts for the way in which they are used.
- *Psychological adequacy*: FG should be compatible with validated hypotheses and well-established findings about human language production and comprehension.
- *Typological adequacy*: FG should be able to provide grammatical descriptions for any natural language and to capture the similarities and differences among them.

Another relevant aspect of Dik's program is the integration of functional and communicative relations in the organization of the model. In particular, FG employs three types of functional relations: semantic functions, pragmatic functions, and syntactic functions. *Semantic functions* specify the roles of participants in a situation or event; they include notions such as Agent (i.e., the entity performing the verbal action) or Goal (i.e., the entity affected by the verbal action). *Pragmatic functions* characterize the status of constituents in a linguistic expression as given or prominent/new information; and *syntactic functions* relate to the perspective from which an event is presented. Thus, in the active sentence *the old elephant is eating an apple*, the event is presented from the point of view of the Agent *the old elephant*, which receives Subject syntactic function. However, in its passive counterpart *an apple is being eaten by the old elephant*, the event is presented from the perspective of the Goal *an apple*, which is promoted to Subject function.

Communicative relations are also integrated in the organization of the model. Dik understands communication as a social activity with which speakers effect changes in the body of general knowledge of their addressees. Those changes may involve two different dimensions. On the one hand, there are those which affect the content of the message in a broad sense and, on the other, those which relate to the relation between speakers and addressees. These two dimensions correspond to the *representational* and *interpersonal* functions (terms

taken from Bühler, 1934, and Halliday, 1970, respectively) and are incorporated as independent levels in the architecture of FG.

Finally, the functional-communicative orientation of the theory is also reflected in the use of the notions *predication* and *reference*, inspired by Searle’s (1969) work, which constitute the building blocks of the grammatical component in FG. Predication is seen as the establishment of a relation among participants or the assignment of a property to an individual. Reference is viewed as a cooperative process with which a speaker guides the addressee to the identification of the entity about which he wishes to predicate something.

The Organization of Functional Grammar

FG is a bottom-up grammar—that is, the generation of a linguistic expression starts with the selection of lexical items from the lexicon component and proceeds upwards to the creation of a complete expression. In accordance with the standard of typological adequacy, FG structures have a clear semantic and pragmatic orientation, as FG practitioners believe that it is from that perspective that a universally valid representation system may be constructed. This means that FG structures contain abstract elements representing linguistic information which will be expressed in different ways across languages. For example, English forms the past tense of regular verbs by adding the suffix *-ed*, whereas German uses *-te* for weak verbs. Both, however, are represented as “Past” in FG structures and converted into the actual form for each language at the end of the derivation.

The theory is divided in three main blocks: the *fund*, which contains both the basic and derived lexemes of a language; the *layered structure of the clause*, which takes care of the construction of grammatical representations; and the *expression component*, which converts the representations created by the grammar into the actual linguistic utterances. Figure 1 offers a simplified picture of the model as given in Dik’s (1997) presentation of the theory.

Figure 1 The general organization of Functional Grammar. Adapted from Dik (1997)

The fund may be informally described as a dictionary as it contains all the lexemes or predicates of a language. It is divided into two main parts—the lexicon, which contains basic lexemes, and the fund itself, which also includes derived predicates created by productive word-formation rules. The standard version of the theory recognizes three types of predicates: verbal, adjectival, and nominal, which are stored in the form of *predicate frames*, structures which define the number and type of obligatory participants or arguments that the lexeme requires. An example of a verbal predicate frame is given in (1).

- (1) give [V] (x_i : <animate>)_{Agent} (x_j)_{Goal} (x_k : <animate>)_{Recipient}

(1) states that the verb *give* takes three argument positions, represented by the variable “ x ” which refers to a first-order entity (roughly individuals and (in)animate objects). The argument variables, which receive different subindices to indicate they designate different entities, realize the semantic functions Agent, Goal, and Recipient (i.e., the entity to which/whom something is transferred). Those positions may include restrictions (e.g., “animate”) which must be satisfied by the lexemes occupying them. The units which fill up an argument position are named *terms* and constitute the structural correlate of the above-mentioned referential function. Just like predicates, terms may be basic (typically proper nouns and pronouns) and derived. Derived terms range from simple units such as *a house* to complex phrases containing adjectives, possessors, or relative clauses (e.g., *the teacher’s magnificent house that he bought last year*). The construction of derived terms simulates a cooperative process in which speakers guide their interlocutors to the identification of entities about which they wish to predicate something. The general schema of term formation is given in (2).

- (2) (Ωx_i : predicate₁ (x_i): predicate₂ (x_i): . . . : predicate_n (x_i))

The variable “ x ” can be modified by *term operators*, represented by the variable Ω , and can in turn be restricted by one or more predicates. Dik (1997, p. 132) offers the following representation as an example of a term expression (d = definite, 1 = singular).

- (3) (d1 x_i : elephant [N] (x_i): old [A] (x_i))
“the old elephant”

In accordance with the dynamic interpretation of term construction, the structure given in (3) could be paraphrased as an instruction from speaker to addressee as follows: “identify a definite singular entity x_i such that the property ‘elephant’ applies to x_i , such that the property ‘old’ applies to x_i .”

The main difference between Dik’s initial presentation of FG in 1978 and the 1989/1997 model was the adoption of a *layered structure of the clause* following the proposal in Hengeveld (1989). On the basis of the study of the alignment and scope of the categories aspect, tense, and mood, Hengeveld proposed a number of layers in the organization of the sentence: the *predication*, the *proposition*, and the *clause*. Each layer would have an ontological correlate according to Lyons’s (1977) classification of entity types. FG representations thus make use of different variables, one for each layer, corresponding to the entity the speaker wishes to describe with the associated structure. Each layer can be further modified through different categories, which are called *clausal operators* if they receive grammatical expression (typically tense, aspect, or mood) or *satellites* if they receive lexical expression (roughly adjuncts or adverbials). Table 1 shows the relevant correspondences.

To illustrate the FG analysis of the sentence with a concrete example, let us consider the representation of the expression *probably, the old elephant is eating an apple in the zoo*. In this

Table 1 Layers, entities, and variables in Functional Grammar

<i>Layer/unit</i>	<i>Type of entity</i>	<i>Variable</i>
Clause	speech act	E
Proposition	possible fact	X
Predication	event	e
Term	individual	x

sentence, the speaker describes one event in which the old elephant engages in the activity of eating an apple. This is constructed on the basis of the predicate frame of the lexeme *eat*, which offers one slot for the Agent of the action and another one for the Goal.

$$(4) \text{ eat [V] } (x_i: \text{<animate>})_{\text{Agent}} (x_j)_{\text{Goal}}$$

It is in the Agent position that the term representation in (3) is inserted, whereas the Goal slot is filled up by the term “an apple,” which is constructed with the nominal lexeme “apple” plus the term operators “singular” (1) and “indefinite” (i):

$$(5) \text{ eat [V] } (d1x_i: \text{elephant [N] } (x_i): \text{old [A] } (x_i))_{\text{Agent}} (i1x_j: \text{apple [N] } (x_j))_{\text{Goal}}$$

The representation in (5) constitutes a basic or nuclear predication, which is further modified in our next representation by the operator Prog (progressive aspect). This completes the description of the event or situation, which is represented by the variable “e”. The event is located in time by the operator Pres (present tense) and in space by the satellite *in the zoo*; note that this satellite is constructed just like any other term expression plus the semantic function Location, which will be converted into the preposition *in* at the expression component.

$$(6) \text{ Pres e: [Prog eat [V] } (d1x_i: \text{elephant [N] } (x_i): \text{old [A] } (x_i))_{\text{Agent}} \\ (i1x_j: \text{apple [N] } (x_j))_{\text{Goal}}] \quad (d1x_k: \text{zoo [N] } (x_k))_{\text{Location}}$$

The representation in (6) closes the representational level, the stage of the derivation at which the content of the message is fully specified. Languages also offer grammatical means through which speakers can present an event or situation in accordance with their communicative intentions. FG captures those means at the interpersonal level. In the derivation of the example at hand, the speaker evaluates the actual occurrence of the event described in (6) as “probable” through the proposition satellite *probably*; note that given that this adverb does not belong into the description of the portrayed event it is formally marked off from the rest of the sentence by an intonation pause. Finally, the whole linguistic expression is characterized as a declarative speech act, which is represented through the clause operator DECL.

$$(7) \text{ DECL E: [X}_i\text{: [Representational level in (6)] (probable [A])}_{\text{Manner}}]$$

FG representations such as (6)–(7) are also enriched with syntactic functions, which would allow for an active or passive expression of the example, and pragmatic functions, with which FG captures the dimensions of new and given information through the assignment of Focus and Topic function to the constituents in the representation. In FG, pragmatic functions are only recognized in a language if they have a formal impact in the clause and are thus considered responsible for special markers or construction types. In English,

cleft-sentences and existential *there*-sentences are examples of constructions motivated by pragmatic function assignment. Hence, a cleft expression such as *it is the old elephant that is eating an apple in the zoo* is due, among other factors, to focus assignment to *the old elephant* in (6).

Finally, the expression component is responsible for converting the information presented in (6)–(7) into the actual linguistic utterance. It comprises two basic sets of rules, *realization* and *constituent order rules*. Realization rules follow a simple general format which assigns a value to a function. For example, the formation of gerundive forms in English would conform to a general pattern in which the operator for progressive aspect takes a verbal predicate as its argument.

- (8) Prog (verbal predicate) = verbal predicate *-ing*

In the representation (6), the application of (8) produces the form *eating* as output. The linear order of linguistic expressions is taken care of by constituent order rules which are also part of the expression component. FG representations are not ordered and merely reflect scope relations through bracketing. The theory postulates *placement rules* which situate constituents in the appropriate position on the basis of general ordering principles and the syntactic and pragmatic status of the relevant unit. Placement rules work in tandem with *functional patterns*, which define possible sentence structures for a given language and provide positions for the units in FG representations. The following are the functional patterns for English declarative and interrogative sentences respectively:

- (9) a. P1 S Vf Vi O X
b. P1 Vf S Vi O X

In these patterns, P1 represents a universal initial position, which is used for special purposes such as the placement of constituents with Topic or Focus function. S and O are positions reserved for units with Subject and Object function, respectively, whereas V, which can be subdivided into finite (Vf) and infinitival (Vi), is the position for the main verb in the clause. Finally, X is the position for other constituents, typically satellites. The units in our example would thus be ordered as follows:

- (10) P1 S Vf Vi O X
The old elephant is eating an apple in the zoo

Similarly, an interrogative *wh*-question would make use of pattern (9b), with the *wh*-element taking P1 position as it expresses focal information.

- (11) P1 Vf S Vi O
Where is the old elephant eating an apple

The expression component is also responsible for the assignment of the relevant intonation and stress patterns to linguistic expressions, which may also be sensitive to the nature of the utterance (interrogative, declarative, etc.) or the emphasis conferred to a given constituent.

Functional Discourse Grammar

Several FG practitioners have felt that the theory is not pragmatically and psychologically adequate (Butler, 1991), and to some extent this has motivated the birth of its successor

Functional Discourse Grammar (FDG), whose full-length presentation is Hengeveld and Mackenzie (2008). As for pragmatic adequacy, some authors noted that the 1997 model contained two major obstacles to progress toward a truly functional theory: (a) the fact that research in FG concentrated almost exclusively on the analysis of the sentence and its constituents, and (b) the lack of integration of FG into a theory of verbal interaction. As for psychological adequacy, the number of studies in FG that make reference to the results of psycholinguistic research is rather limited, which means that the theory has remained untested from a psycholinguistic point of view.

Accordingly, although FDG shares with FG the same methodological assumptions and organizational properties, it also presents two major differences: its discourse motivation and its top-down orientation.

FDG notes that a considerable number of grammatical phenomena relate to units that are either larger or smaller than the clause and for that reason cannot be adequately described by a sentence grammar. In particular, many verbal exchanges are not realized in the form of fully fledged sentences, but rather in the form of fragments, or nonclausal units. Hence, FDG replaces the sentence with the *discourse act* as a basic unit of grammatical analysis. The following utterances are examples of nonsentential discourse acts.

- (12) a. John!
 b. A pen.
 c. To the market.

The expression in (12a) may act as a vocative or address to initiate a verbal interaction, whereas (12b) and (12c) can serve as natural replies to a question. Hence, apart from their nonsentential nature, what these expressions have in common is that they serve as complete contributions to discourse interaction and must obviously be studied within the context in which they occur. At the same time, there are linguistic phenomena that relate to the organization of connected discourse and extend their influence over several sentences and cannot be properly understood by analyzing isolated expressions.

A second difference between these models relates to their architectural orientation. Unlike FG, FDG is a top-down grammar in which the generation of a linguistic expression starts from a communicative intention which ultimately leads to the grammatical coding of a piece of information and its final articulation or execution. The top-down organization of FDG is a reflection of its commitment to the standard of psychological adequacy and is strongly inspired by the psycholinguistic work of Levelt (1989).

Finally, and with an aim to integrate the grammar component in a theory of verbal interaction, FDG includes two adjacent components to grammar proper: the conceptual and the contextual components. The *conceptual component* is responsible for the creation of a communicative intention and the construction of a preverbal message, i.e., a conceptual structure that will serve as input to the grammar. The *contextual component* represents the speech situation and includes both linguistic and nonlinguistic perceptual information that is potentially relevant for the creation of new communicative intentions and conceptualizations. FDG, as a linguistic theory, is centrally concerned with the grammatical component, and reference is made to the adjacent components as far as they are relevant in accounting for linguistic phenomena. For example, in Spanish the sex of speakers may be relevant for choosing the appropriate gender marker in an expression.

- (13) a. Estoy cansado
 'I'm tired'; (male speaker)
 b. Estoy cansada
 'I'm tired'; (female speaker)

Hence, the choice of the relevant suffix is dependent upon properties of the speech situation which are captured at the contextual component. Similarly, information contained in the conceptual component may be relevant for understanding grammatical and lexical choices. Thus, the use of the pronoun “it” in an expression like *it is eating an apple in the zoo* will only be communicatively felicitous if the addressee can find out the referent of the pronoun; the speaker tacitly assumes that the individual the pronoun refers to will be identifiable for the addressee (typically because it has been introduced previously in the discourse). This assumption is made at the conceptual component and motivates the choice of a pronoun over a proper noun or a complex term.

García, Ofelia

MARÍA E. TORRES-GUZMÁN

Ofelia García, Professor in the PhD Program in Urban Education and Hispanic and Luso-Brazilian Literatures and Languages at the Graduate Center at the City University of New York, is a renowned international scholar in the fields of bilingual and multilingual education, the education of minoritized language groups, language policy, and the sociology of language. She emigrated from Cuba as an 11-year-old in 1961 and began her career as a bilingual/ESL teacher in New York City in the early 1970s. Her work in institutions of higher education began in the late 1970s when she became an instructor at SUNY, Old Westbury, while she worked on her doctorate, which she received in 1981 from the Graduate Center, City University of New York, in the area of Hispanic and Luso-Brazilian literatures and languages. García has taught at various New York-based institutions—Yeshiva University, the City College of New York, the Brooklyn Campus of Long Island University, and Teachers College, Columbia University—and completed two postdoctorate fellowships in sociology of language and bilingualism in 1981 at Yeshiva University and in the Institute of Political and Social Science Research at the University of Michigan, Ann Arbor, in 1990. Her academic career was briefly interrupted by a five-year stint as the Dean and academic leader of Long Island University, Brooklyn Campus.

Her numerous edited volumes, 84 articles, two recent coauthored books, as well as her recent *Bilingual Education in the 21st Century* (García, 2009) are a testimony to a very healthy scholarly life.

García's initial academic interest was in the area of Spanish literature from a socio-linguistic perspective—in poetry, in Cuban and in Puerto Rican literature. She published during this period, for example, *Veinte años de literatura cubano-americana*, with Silvia Burunat (Burunat & García, 1988), and “La problemática del idioma en el ensayo puertorriqueño” (García, 1984). The significantly emergent issues of the mid to late 1980s—language variations in Latino communities and bilingual education—had an impact on her thinking and writing at this time. During this period, she coedited *English Across Cultures, Cultures Across English* (García & Otheguy, 1989), and *U.S. Spanish: The Language of Latinos* (Wherrit & García, 1989). Both of these books illustrate her language base beginnings, but the literary concerns, while continuing until the end of the 1980s, began to turn toward the socio-linguistic aspects of language. In this period, she also examined language attitudes, intergenerational shifts, and the ethnic press primarily within the New York City Latino communities.

She also tackles the sociological issues of language in educational settings, that is, within bilingual education. Her initial work in this area is within the educational settings among Cubans in the Miami area. Her *focusschrift* (García, 1991) in honor of Joshua A. Fishman, her mentor, positions her within the pioneers of languages in schooling from an international perspective. She works in the fields of sociology of language, sociolinguistics, language planning, and language policy. In this area, she is known for the metaphor of the language garden when she compares attending to the multiple languages children bring into schools to the gardener who attends to different types of flowers in the garden, and to multilingualism as the beauty of the many colors of a well-designed garden. In her writing, García's ability to capture the essence of the concepts she wants to communicate

in image forms, and her knack for capturing appropriate and contemporary images, became a trademark.

Upon leaving the deanship of Long Island University, Brooklyn Campus, she joined Teachers College, Columbia University where the mark of a new era of transformation begins. One of the first pieces of writing that illustrate this new stage in her life is "Lost in Transculturation" (García, 2006) where she considers how the movement of people and things globally begin to show up in the shifts of immigration and how these are manifested in the transformations of the field of bilingual education models such as dual language education. This period was extremely productive as she began to consider new ways of thinking about issues of language in classrooms.

One can think about the transformations in three ways. García's work with Gregorio Luperon High School, a Latino Newcomer School that receives new Spanish-speaking immigrant children, was the site for work with colleagues, like Lesley Bartlett, through which they painstakingly document a speech community model of bilingual education where hybrid linguistic practices assist the children in their translocal world. This work, jointly with Lesley Bartlett, is covered in an article entitled "A Speech Community Model of Bilingual Education" (García & Bartlett, 2007) and in a forthcoming book (Bartlett & García, in press).

A second direction of García's work is in challenging the international world to imagine multilingualism in new ways. The Language Symposium at Teachers College Columbia University, cochaired with María E. Torres-Guzmán, was an event from which two books emerged. The first was *Imagining Multilingual Schools* (2006), coedited with Tove Skutnabb-Kangas and María E. Torres-Guzmán. The second is *Global Perspectives on Multilingualism* (2009), by María E. Torres-Guzmán with Joel Gómez. The result of these volumes is a survey of what exists as understandings of multilingualism and how globalization calls for transformations within the field. While the main focus continues to be language planning and language policy, the emergence of policy in the context of classrooms is innovative.

Lastly, she began to focus on redefining and reinventing ways of speaking about what is occurring in classrooms. With Jo Anne Kleifgen and Lori Falchi, she examined issues of equity and redefined how to speak about children in bilingual classrooms, moving from the parochial "English-language learners" to a more descriptive term, "the emergent bilingual." This work is found in *Equity in the Education of Emergent Bilinguals* (García, Kleifgen, & Falchi, 2008) and was part of the Educational Equity Campaign at Teachers College, Columbia University. It is also the basis for her book, coauthored with Jo Anne Kleifgen, *Educating Emergent Bilinguals* (2010).

In addition, in her work with kindergarteners and elementary children in New Rochelle bilingual schools, García documents her seminal work on translanguaging, where she consolidates new critical sociocultural theoretical ways of thinking about bilingual learning processes. Translanguaging proposes a definition of "sense-making" from the speaker's rather than from a language perspective, from a bilingual rather than a monolingual speaker's perspective, and it embraces all student or teacher uses of bilingual/multiple discursive practices.

This work on translanguaging in classrooms emerges from García's theoretical framework of bilingualism in the 21st century as *dynamic* (and not simply subtractive or additive). This conceptualization, documented with cases from around the world, is best found in *Bilingual Education in the 21st Century* (García, 2009). She continues this work, emphasizing the urban context, at the Graduate Center, CUNY.

Most recently García has published two coedited books: *Negotiating Language Policies* (Menken & García, 2010) and *The Handbook of Language and Ethnic Identity* (Fishman & García, 2010). A second volume of the latter book, focusing on the success-failure continuum

of language and ethnic identity efforts, is in press. She is presently involved in a large-scale research project on Latino students in New York City high schools.

Gass, Susan M.

CHARLENE POLIO

Susan M. Gass (1943–), born in Boston, Massachusetts, is a university distinguished professor in the department of linguistics, and Germanic, Slavic, Asian, and African languages at Michigan State University in East Lansing, Michigan. A well-known and prolific scholar in the area of second language acquisition (SLA), she has also held several administrative positions at Michigan State University including director of the English language center and founder and director of the PhD program in second language studies. She received the Paul Pimsleur Award for Outstanding Research given by the American Council for the Teaching of Foreign Languages in 1996, and in 2002 she was chosen as the recipient of the American Association for Applied Linguistics (AAAL) Distinguished Scholarship and Service Award. She has been the president of both AAAL (1986–7) and the *Association Internationale de Linguistique Appliquée* (2002–8). With Larry Selinker, she has authored what is probably one of the most widely used textbooks in the field of SLA, *Second Language Acquisition: An Introductory Course*, whose third edition was published in 2008. She has also edited two series, *Second Language Research: Theoretical and Methodological Issues* with Jacquelyn Schacter and *Research Methodological Issues* with Alison Mackey. Gass has served on several editorial boards including *Applied Linguistics* and *Studies in Second Language Acquisition*, the latter of which she continues to serve as associate editor. Gass completed her BA in Italian at the University of California, Berkeley, followed by an MA in Italian at Middlebury College in Vermont. After working in Italy, she received an MA in linguistics at the University of California, Los Angeles followed by a PhD in linguistics at Indiana University.

Universals in SLA

Gass's dissertation, the results of which were published in 1979 in *Language Learning* (Gass, 1979), was one of the first studies to examine universal tendencies in SLA. In other words, certain patterns of learning were found to be common across learners with a variety of first and second languages. With regard to the acquisition of relative clauses, Gass found that learners followed developmental sequences that would be predicted by Keenan and Comrie's (1977) noun phrase accessibility hierarchy. Gass's research has been widely cited and related findings were confirmed in other studies. Research continues on relative clauses in second language acquisition with other researchers questioning whether the noun phrase accessibility hierarchy can account for development in Asian languages or written language. As for other linguistic universals, including those suggested by formal approaches and universal grammar, Gass (1997) has claimed that the study of such universals in SLA are not mutually exclusive with approaches that focus on interaction as driving language learning. Indeed, such linguistic universals may simply constrain language learning.

Research Methods

Gass has published several articles on research methods (e.g., Gass, 1994, 2001) including a call for more detail in reporting research to enable replication in SLA (Polio & Gass,

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

© 2013 Blackwell Publishing Ltd. Published 2013 by Blackwell Publishing Ltd.

DOI: 10.1002/9781405198431.wbeal0445

1997). She has also authored three books on research methods. *Stimulated Recall Methodology in Second Language Research* (2000), coauthored with Alison Mackey, paved the way for researchers to include stimulated recall as a technique to more deeply investigate SLA learning processes. Gass's research on learners' perceptions of recasts (Mackey, Gass, & McDonough, 2000) was one of the earliest SLA studies to use such a technique. She has published two other books on research methods, *Second Language Research: Methodology and Design* (with Alison Mackey, 2005) and *Data Elicitation for Second and Foreign Language Research* (with Alison Mackey, 2007b). She continues to edit books in her research methods series that have included topics such as case study research, priming, and thinking aloud.

Interaction Research

While an assistant professor at the University of Michigan in Ann Arbor, Gass began investigating the role of interaction in second language learning, the area that she is now best known for. Work on the role of interaction had started at UCLA with Evelyn Hatch and Michael H. Long, who claimed that language ability developed through learning to communicate. Gass, however, had not collaborated with either, having left UCLA in 1976. With Evangeline Varonis, she published two studies on non-native-speaker comprehensibility (Varonis & Gass, 1982; Gass & Varonis, 1994). The link between interaction and the ability of non-native speakers to understand and be understood was emerging as a major factor in language learning. In 1983, Gass co-organized the tenth Conference on Applied Linguistics, entitled *Language Input: Learners' Use and Integration of Language in Context*. Some of the papers from this conference resulted in a coedited book, with Carolyn Madden, which included several influential chapters, including Merrill Swain's paper on the role of output in second language learning. One of Gass's most influential studies (Gass & Varonis, 1994), published in *Studies in Second Language Acquisition* was one of the first to show empirically a link between negotiation and learner production in a short-term study. Others (e.g., Pica, 1994) went on to postulate why negotiation might aid learning and what the possible long-term learning effects of interaction might be. Many other studies have gone on to demonstrate the link between interaction and longer-term development.

Gass continued to publish on the role of interaction and to explore how different variables affect interaction and the outcomes of interaction, including how the ordering of input and interaction can affect the learning of different areas of language (Gass & Alvarez-Torres, 2005) and how heritage and nonheritage learners perceive interactional feedback differently (Gass & Lewis, 2007). Along with Alison Mackey (Gass & Mackey, 2006, 2007a), Gass wrote two overviews of the interaction approach that in particular highlighted the relationship of interaction to input, output, and feedback, as well as the importance of attention. In 2009, a volume edited by Alison Mackey and Charlene Polio on interaction was published in Gass's honor.

Although she described the interaction approach as having some properties of a theory (Gass & Mackey, 2007a), Gass has never claimed that an interaction approach to SLA is a complete and causal theory of SLA. Indeed, she has acknowledged that frequency (such as in usage-based approaches) may be significant (Gass & Mackey, 2002) as well as universal constraints (Gass, 1997). Responding to a critique of her research (and of other more cognitively oriented research) by Firth and Wagner (1997), Gass (1998), using the apples and oranges analogy, explained that social views of language are most definitely not incompatible with the more cognitive approaches taken in much of the interaction research. Indeed, this complex interplay of cognitive factors (e.g., working memory), social factors (e.g., relevance of the interaction), contextual factors (e.g., frequency), and affective factors (motivation) have all been related to interaction in the learning process.

Other Publications

Gass continues to produce publications that provide overviews of the field of SLA (Gass, 2009a, 2009b). In addition to the introductory SLA textbook, Gass continues to work on additional overviews of the field. *The Handbook of SLA*, to be published by Taylor & Francis/Routledge, is a 35-chapter handbook coedited with Alison Mackey. Another edited volume with Alison Mackey on research methods in SLA is currently in progress for Wiley-Blackwell.

Gee, James

TOM RANDOLPH

Introduction

James Paul Gee (1948–) is a preeminent cross-disciplinary analyst and researcher of human learning. Blending passions for applied linguistics and education throughout his career, Gee has also done research in psychology, cognition, anthropology, and communication. He has been a prolific and innovative discourse analyst since the early 1980s, but first became widely known for his pioneering work in new literacy studies (NLS), which replaced a traditional understanding of “literacy” with a sociocultural one (Barton, 1994; Street, 1995; Gee, 1996). He has since followed that research thread to the impact of digital literacies in and out of the classroom. To widespread critical acclaim and popularity, Gee’s work is currently reimagining “school” in light of 36 learning principles shared by all good video games (Gee, 2003c, 2005b, 2007). He has authored 13 books, several of which have seen multiple editions, coauthored three others, and his research has been published in more than 150 scholarly articles, book chapters, reviews, and handbooks. He has served on the editorial boards of *Anthropology and Education Quarterly*, *Cognition and Instruction*, *Critical Inquiry in Language Studies*, and *Digital Culture and Education*. His work has been funded by numerous grants from the Spencer and MacArthur foundations. A representative collection of papers and other work is at www.jamespaulgee.com/publications.

Academic Background

James Paul Gee was born in 1948 in San Jose, California, and completed all of his formal education in that State. After studying liberal arts, Latin and Greek, he earned his first formal degree in Philosophy in 1970 from the University of California at Santa Barbara. Four years at Stanford University’s School of Education and Department of Linguistics culminated in a terminal degree in Linguistics in 1975.

Though his professional academic career began with positions as a Chomskyan (briefly, linguist Noam Chomsky’s belief that all people “share the same biological capacity for human language” [Gee, 2003b, p. 4]) theoretical linguist at Stanford University and Hampshire College, the “social turn” (Gee, 1999) of his research gained momentum in the early 1980s when he took a position as an applied linguist in the School of Education at Boston University in 1982, where he started new graduate programs that adopted an integrated approach to language and literacy. At the personal (internal) level, Gee (2003b) describes the “social turn” as a battle of identities; on the professional level, his ongoing analysis of the social and cultural aspects of language while both the theoretical and applied linguistics camps declined to accept him underscored the validity of his perspective on society; simply put, Gee sees the most useful view of society as being made up of individuals negotiating degrees of membership in multiple “Big D Discourses,” where discourses are ways of interacting with language and all other mediational means (Wertsch, 1998) such as technologies, texts, clothing, and other people, so as to construct one identity or another. Such a perception of social practice revealed the need to reconceptualize

linguistic research and discourse analysis (the study of language in use) in particular. In *Social Linguistics and Literacies: Ideology in Discourses* (Gee, 2007), “literacy” becomes a count term, each literacy being multimodal and situated or embedded uniquely in one discourse (Gee, 1989), and all linguistic meaning (and by extension all relevant linguistic analysis) is seen as situated in the social practices of people constructing and negotiating multiple identities within and across multiple discourses. While the Tashia Morgridge Professor of Reading at the University of Wisconsin at Madison, Gee wrote a definitive guide to the field, *An Introduction to Discourse Analysis: Theory and Method* (Gee, 2010), which is now a leading academic resource.

This theoretical and methodological perspective has guided James Paul Gee’s career ever since, and is arguably the key element of new literacy studies. NLS and other research movements (Gee identifies 13 in Gee, 1999, including ethnomethodology, situated cognition, cognitive linguistics, connectionism, and postmodernism) view the mind as a social entity embedded in the world, rather than the largely private one favored by behaviorists, and the mind’s learning as occurring entirely through pattern recognition from experiences situated within discourses. In *The Social Mind: Language, Ideology, and Social Practice*, Gee (1992) describes how memories, beliefs, and other seemingly “private” mental objects are constructed in a sociocultural context that is inherently ideological and political, and how through self-deceptive narratives, people tend to privilege the discourses of which they seek to be recognized as members. His collaboration as a critical discourse analyst—CDA is an analysis that recognizes that all language is social and political, and all research and analysis grounded in the perspective of the researcher (Gee, 2003a)—in *The New Work Order: Behind the Language of New Capitalism* (Gee, Hull, & Lankshear, 1996) written while holding the Jacob Hiatt Chair in Education at Clark University, explores the language of the global discourses of the New Capitalism and their implications for schools and literacy. While at Clark, Gee’s decade-long focus on an integrated theory of language, literacy, and schooling provided the framework for several school-based projects run by the Hiatt Center for Urban Education at Clark University, and a Spencer Foundation funded after school science project.

Throughout his career, James Paul Gee has been concerned with the relationship (or lack thereof) between how people learn in and out of schools; more specifically, he has used discourse analysis to identify why some (usually underprivileged) children fail school, while others succeed (See Gee, 2003b), and, as digital literacies have materialized in the past two decades, answered this question by arguing strongly for a pedagogical shift in American schooling toward game-style domain (formerly “discourse”)-based experiential learning. He points out that to stay in business, game producers have to get a lot of people to choose to learn the skills and tools (what Gee calls “the design grammar” [Gee, 2002]) needed to solve extremely complex and rigorous problems situated within the semiotic domain of a particular game. A semiotic domain is the set of one or more modes of interaction (e.g., oral or written language, gestures, sounds, symbols) used by the group of people who identify themselves as members of a domain to communicate distinctive messages to each other. Gee argues that academic content (including and perhaps especially linguistic), such as biology facts, is more deeply and usefully learned as a by-product of becoming literate in the social language (the discourse, or register, or linguistic style) and semiotic domain of biologists (Gee, 2005a). In other words, biology is a “game” that certain types of people learn to “play.” (Gee, 2005a, p. 34)

In 2003, Gee published *What Video Games Have to Teach Us About Learning and Literacy*, which described 36 principles that distinguish good learning games, and argued that American schools needed to embrace these principles if they hoped to graduate the digitally literate students who would be able to succeed in America in the 21st century (Gee, 2003c). Since 2007, James Paul Gee has also been the Mary Lou Felton Presidential

Professor of Literacy Studies in the Department of Curriculum and Instruction at Arizona State University, and his research has been supported by four MacArthur Foundation grants. He is currently researching the Our Courts: 21st Century Civics Project (www.ourcourts.org) as a member of the technology and design team.

Major Contributions and Ideas

Gee's work in discourse analysis provided a model of interdisciplinary linguistic research, and as such *Social Linguistics and Literacies: Ideology in Discourses* in 1990 was a founding text of the new literacy studies, and a major contribution to the nascent field of sociocultural approaches to language and literacy (Gee, 1990). His specialization as a linguist differentiates him from other experts in situated learning, and some of his unique contributions are his analyses of situated language that reveal the inequities among discourses. For example, Gee demonstrates the significance of an individual's primary discourse, the "ways with words, deeds, things, thoughts, and feelings that, as children, we associate with being a 'person like us' (like our socializing group)" (Gee, 2003b, p. 15), on success in school by analyzing an African American child's linguistic prowess as a storyteller to discover why she was judged a failure at language by her Anglo teacher, who had a different set of linguistic expectations. Gee described a number of "secondary discourses" prevalent in schools, and showed how some families' social practices, such as dinner table reporting, build a base for literacy in school-based secondary discourses (with their specialist varieties of language) into their children's primary discourses (and vernacular language), and some families' social practices do not. Thus Gee identified American schools as institutions that privilege certain types of identity formation, and recognize (grant particular status to) different identities in different ways, and American school students as people who feel either that they are suited for school, or they aren't.

Gee further contributed to the dialogue on school reform by developing the implication of this work into a research agenda that has impacted numerous disciplines connected to literacy, cognition, and education. The primary implication for schools of a discourse (now domain)-based view of literacy is that all meaning, whether in the world or in texts, is situated in the moments of learners' experiences, that if learners are to use schools to learn to think and act in the world, they must experience the world in school. In other words, schools must provide students with scaffolded (sequenced in increasing cognitive complexity) apprenticeships and interaction with more- and less-literate peers and masters of non-school domains (Gee, 2000), so that they can become literate in the social languages (registers or styles of natural languages), design grammars (the multimodal syntax of the domain), and other semiotic modalities of those domains. Gee's work in the past decade has been toward integrating children's passion for and literacy in digital media with the needed education reform.

Gee's perspective on semiotic domains further specifies the role of language in society and the requirements for sociolinguistic literacy. Each semiotic domain uses a different social language with its own vocabulary and syntax, discourse and pragmatic systems. One learns the domain's social language by learning to situate ever more complex meanings in that domain, beginning the process by apprenticing to more masterful members, and ultimately approaching mastery and insider status oneself if the process is not broken off. Through this lens Gee shows language to be inextricable from the other modalities (e.g., equations, symbols, images, gestures, artifacts) and practices of people claiming varying degrees of membership in the domain's "affinity group" (Gee, 2002). Thus, "authentic learning" is "learning that leads to mastery of the semiotic domain's design grammar and growing membership in its associated affinity group" (Gee, 2002, p. 3).

Such a view places Gee himself in the situated learning affinity group (see Lave & Wenger, 1991), and reveals why Gee sees the simulation approach of good video games, which immerses novice gamers in semiotically rich and authentic virtual worlds (semiotic domains) and through repeated plays scaffolds their literacy in the domain toward mastery, as one obvious solution to the education crisis. In *What Video Games Have to Teach Us About Learning and Literacy* (Gee, 2003c), he derives 36 learning principles from his study of the learning a game player undertakes when mastering a new game, and expands his suggestions for education reform beyond video gaming to include “games” that honor these principles. These principles cover learner-participation conditions that replicate real-world language learning, including active and critical participation in at least a subset of a real domain from the outset, interconnectedness of multimodal semiotic systems and texts within and perhaps across semiotic domains, embodied experience of texts in multiple social identities, and authentically motivating and concentrated social practice. An Internet search reveals that these principles have been taken up by videogame designers, educators, and graduate students worldwide in multiple modalities and media.

Gender and Second Language Acquisition

JULIA MENARD-WARWICK

Research on gender and language learning has generally followed larger trends of gender theory in applied linguistics. Thus, over the past several decades, such research has often been situated within what Cameron (2005) terms the *difference* paradigm of language and gender research, concerned with overarching linguistic differences between men in general and women in general (in contrast to a more explicitly feminist *dominance* paradigm, which has researched women's subordination through language). However, more recent language and gender research has come to emphasize a third paradigm: gender *diversity*, which seeks local explanations for observed differences between men and women in particular contexts (Eckert & McConnell-Ginet, 2003; Cameron, 2005).

Contemporary researchers in applied linguistics have come to define gender as "a system of social relations and discursive practices" (Pavlenko & Piller, 2001, p. 17). Thus, current theory sees gender not as an essential attribute of the individual human being, but rather as a way for people to position each other in socially meaningful (and often stereotypical) categories such as "men," "women," "jocks," or "homemakers" (Eckert & McConnell-Ginet, 2003). These gendered categories, sometimes referred to as subject positions, exist in relation to each other (e.g., "homemaker" in relation to "breadwinner"), and in relation to gendered institutions, such as schools or corporations. Each category additionally involves forms of social action (practices), such as playing football or watching soap operas. These practices can be seen as discursive in that they connect to social discourses, characteristic ways of referring to and evaluating common topics, such as sexuality or education (Fairclough, 1992). Considering gender from this perspective, it is important to remember that gendered social relations and discursive practices vary markedly across social contexts and situations of use; that they are historically and socioculturally specific; and that they may be resisted as well as embraced by individuals or social groups.

In coming to view gender in this fluid and dynamic way, applied linguistics has moved away from previous attempts to identify universal contrasts between "men's language" and "women's language." Exemplifying this earlier approach, Green and Oxford wrote in 1995, "If gender differences appear in many studies across different cultures, this suggests that biological and/or socialization-related causes for these differences might exist and that these causes might have a real, if subtle, effect in the language classroom" (p. 266). In their study of L2 learning strategies among university English students in Puerto Rico, they found, for example, that female students were significantly more likely to use what they refer to as "rather global strategies" (p. 289), such as "skim then read carefully," a finding which they connect to previous research on women as "global learners." Interestingly, the one strategy used more often by men, "watch TV or movies in English," was explained as due to the fact that English-language programming in Puerto Rico was dominated by sports coverage (popular with men), while women were more likely to watch Spanish-language soap operas (telenovelas).

Green and Oxford's argument that "gender difference trends in strategy use are quite pronounced within and across cultures" (1995, p. 291) is based on extensive research. Nevertheless, as Chavez points out in a discussion of this research, "it becomes difficult

2 GENDER AND SECOND LANGUAGE ACQUISITION

to compare findings across studies [due to] . . . a lack of consistency in labels and corresponding definitions" (2001, p. 177). The picture that emerges from a broad literature review into gender differences in language learning (e.g., Chavez, 2001) is that differences between male and female language learners are easy to find—but that these differences tend to be inconsistent across contexts. For example, contrary to Green and Oxford's 1995 contention that women tend to be more "global" learners than men, Brantmeier (2003) found men more likely to use "global" strategies than women for L2 reading comprehension—but only when reading a passage designated by the researcher as "male-oriented" (chosen to appeal to stereotypically masculine readers).

Such research on gender and language learning often notes the theoretical distinction between "gender" (masculine/feminine) as cultural and "sex" (male/female) as biological, but may nonetheless conflate the two concepts as synonymous in practice, as in Brantmeier's (2003) use of the term "male-oriented," which implies that men by nature of their biology will be interested in reading about boxing. Even researchers such as Chavez (2001), who argue that gender differences result from socialization, nevertheless have some tendency to look for patterns of gender difference on small cognitive measures (such as the amount of correct vocabulary identified on listening comprehension tests), and then to explain these differences as perhaps due to common socialization practices across "European-American" communities.

Cameron's "gender diversity" paradigm (2005), in contrast, avoids such sweeping generalizations, and prioritizes local explanations for observed gender differences. A good example of such an observed difference would be the tendency among the Puerto Rican men who filled out Green and Oxford's 1995 survey to watch sports on English-language cable television—a practice that could potentially have a helpful effect on their listening comprehension in English. Of course, gendered discursive practices such as watching television sports coverage often transcend local contexts, but also vary significantly between and within them, depending on a number of social factors, from language proficiency to social class. Because of this variability in local realizations of gender, it has become common to discuss "masculinities" and "femininities" as plural terms (Eckert & McConnell-Ginet, 2003; Cameron, 2005).

Since the beginning of the 21st century, researchers have begun to examine how learners' gendered identities shape and are shaped by their L2 development (e.g., Pavlenko, Blackledge, Piller, & Teutsch-Dwyer, 2001; Davis & Skilton-Sylvester, 2004; Langman, 2004). Although identity is a word with many definitions, it is useful to see identity within language-learning contexts as "a way of talking about how learning changes who we are and creates personal histories of becoming in the context of our communities" (Wenger, 1998, p. 5). Moreover, because individuals often belong to multiple communities and may have multiple roles and relationships even within small social groups, identities are best conceptualized as multiple rather than unitary. A number of studies show that when learner identities are discounted, resistance rather than learning is likely to result (e.g., Norton, 2000). Likewise, when language and literacy development become congruent with learner identities, learning is enhanced (e.g., Ibrahim, 1999). Because gender affects group participation (Eckert & McConnell-Ginet, 2003), identity development tends to be highly gendered, as is the situated learning that occurs from participation in discursive practices (Wenger, 1998).

In a review of ethnographic findings on multilingualism and gender, Ehrlich found that speakers' acquisition of language varieties often depended on participation in cultural and workplace practices that varied by gender: "Men and women may have differential attitudes towards and concomitantly differential motivation and incentive for learning or using languages . . . depending on the particular way that gender identities and gender relations are constituted in that community" (1997, p. 430). In this regard, some studies of immigrant

women and families have emphasized the gendered constraints that work against language and literacy development. For example, in Rockhill's (1993) research in a southern California Latino community, she found that men had more opportunity to learn English in the workplace, and that family pressures, including domestic violence, kept many women from pursuing English-language education. Similarly, in a study of Portuguese factory workers in Canada, Goldstein (1997) observed that men's mechanical or technical positions at work enabled them to improve their English through contact with non-Portuguese speakers, whereas women's labor on the production lines tended to segregate them in a monolingual Portuguese environment.

In contrast to the above authors' emphasis on how the gendered practices of immigrant communities can impede women's language learning, Norton's study of immigrant women in Canada (Norton Peirce, 1995; Norton, 2000) significantly introduced a new concern with language-learner agency. For example, Norton illustrates how one woman drew strength from her maternal identity to overcome anti-immigrant prejudice: having come to Canada so that her children could have a better future, Martina used her developing English skills to keep contemptuous coworkers or unscrupulous landlords from jeopardizing her family's finances. In Norton's analysis, when mainstream Canadians employed a discourse that positioned immigrants as ignorant and exploitable, Martina was able to "set up a counter-discourse . . . by resisting the subject position immigrant woman in favor of the subject position mother" (2000, p. 127).

Norton's focus on agency, as well as on the ways that gendered identities, practices, and discourses affect language learning, has continued in subsequent ethnographic studies. For example, in McKay and Wong's 1996 study of Chinese immigrant youth in California, one boy's identity as a popular athlete facilitated making friends with English-speaking classmates; this improved his speaking skills but gave him less reason to focus on academics. Ibrahim (1999) wrote about Francophone African youth in Canada who acquired English through participation in practices and discourses of hip-hop—within an environment where identities such as "rapper" or "DJ" were more open to young men than to their female counterparts. In contrast, when Gordon (2004) studied a Lao refugee community in Philadelphia, she found women learning more complex English than their husbands through their gendered participation in "domestic events," such as interacting with school personnel, selling used cars, and advocating for their children in the juvenile justice system.

Indeed, going beyond Ehrlich's (1997) contention that men's and women's language learning depends on the gendered practices of their communities, Menard-Warwick (2009) argues that L2 learning is more crucially shaped by the ways in which individuals respond to the gendered discourses of their families and local communities. In an ethnographic study, she contrasts two Latina immigrants in California, one of whom began studying English at home after her husband convinced her that she needed the language to protect her children from urban perils—while the other acquired English in the workplace after a long battle with her husband who believed her place was in the home. Hruska (2004) has a similar focus on learner agency within an overall context of male dominance. In a study of English learners in a US kindergarten, she found that the child whose L2 skills developed the most was a boy who managed to transcend gender binaries and make friends with both male and female classmates. Conversely, Teutsch-Dwyer (2001) chronicled how the masculinities of a Polish immigrant in California tended to limit his lexical and grammatical acquisition as his conversational participation was scaffolded by overly supportive female coworkers.

Although the above studies all consider gender in North American immigrant communities, similar gendered trends have been found in other learning contexts. Western women in Siegal's 1996 study found the gender roles encoded in Japanese phonology and morphosyntax to be in conflict with their own assertive subjectivities. As one said about

4 GENDER AND SECOND LANGUAGE ACQUISITION

a Japanese female acquaintance, "I cannot stand the way she talks. She is so humble all the time. I don't want to be that humble" (p. 356). Therefore, in Siegal's analysis, these learners' identities conflicted with the acquisition of pragmatic competence in Japanese. In widely cited research on study-abroad students in Russia, Polanyi (1995) found that female students' contact with Russian speakers was severely limited by experiences of sexual harassment, and as a result women did not develop oral skills to the same extent as the men in their study-abroad group. Talburt and Stewart (1999), in a case study of an African American student in Spain, additionally noted that these problems of sexual harassment can be intensified by racism.

In studies of foreign-language learning, Sunderland (2000) and Carr and Pauwels (2006) contrast the experiences of boys and girls in classrooms in England and Australia respectively. Both found that boys' participation in classroom interaction was constrained by gendered discourses of masculinity that saw language learning as a feminine field. While some teachers in Carr and Pauwel's study were able to counteract these discourses by engaging boys in active learning through Internet technology or drama, even boys who were dedicated language learners felt social pressure to concentrate on more "masculine" pursuits such as sports or science. As a young male participant in Sunderland's study claimed, "boys have a limit what [*sic*] they can do" (2000, p. 168). As a result, Sunderland argues that "the type of femininity being 'performed' or constructed in this class by the teacher and the girls was a distinctly academic one relative to the boys' masculinity" (2000, p. 168).

Here Sunderland cites Butler's theory of performativity (1999), which has profoundly influenced gender studies over recent decades, but which has inexplicably been little used in studies of gender and language learning. Introducing language and gender studies, Eckert and McConnell-Ginet write that gender should be seen not so much as something that people have, but rather as something that people do: "Gender doesn't just exist, but is continually produced, reproduced, and indeed changed, through people's performance of gendered acts" (2003, p. 4). While L2 scholarship has paid little attention to this theoretical perspective, a number of current scholars in the related field of literacy research describe individuals "performing" gender in literacy events and practices (Blackburn, 2002–3). For example, Finders (1997) describes a clique of early adolescent girls who enacted a "normal teenager" version of femininity through such literacy practices as writing notes in class and reading fashion magazines. Similarly, Dutro (2002–3) shows how boys performed masculinity through public choices of reading materials in their fifth-grade class. These studies emphasize powerful connections between learning and identity, demonstrating how literacy development becomes particularly intense when it enacts valued identities (Blackburn, 2002–3). Applications of this theory to studies of L2 learning would be a valuable direction for future research.

To conclude this discussion, it is clear that much of the research on L2 acquisition and gender can be classified within two early paradigms of language and gender research (Cameron, 2005): either a feminist focus on men's linguistic dominance over women (e.g., Rockhill, 1993) or a less political emphasis on gender differences (e.g., Green & Oxford, 1995). However, since the emerging picture of gender and L2 learning across a number of studies is considerably more complex than either of these paradigms might allow, research into gender and language acquisition has necessarily begun adapting itself to Cameron's third paradigm (2005), that of gender diversity. Thus, we can look forward in future to research on gender and SLA in even more diverse linguistic contexts, including study-abroad programs, foreign-language classrooms around the world, online communities, intercultural families, and immigrant neighborhoods. It would be helpful if, as in Deutsch-Dwyer's 2001 study, more of this research balanced detailed descriptions of learners'

gendered social contexts with close analysis of their specific trajectories of linguistic development (lexical, grammatical, pragmatic, etc.). We can additionally hope that this research will increasingly demonstrate an ever greater theoretical sophistication drawn from the larger fields of applied linguistics and gender studies.

Generalizability Theory in Language Testing

ATTA GEBRIL

Introduction

Reliability investigation in educational measurement, and consequently in language assessment, primarily focuses on estimating the consistencies and inconsistencies in test scores. The question here, as Lado (1961, p. 31) puts it, is whether “a test yields the same scores one day and the next if there has been no instruction intervening.” Examples of possible sources of inconsistencies could be test administration conditions, test content, or raters. Classical test theory (CTT) has been traditionally used to examine score reliability since the beginning of the 20th century (Traub, 1997). In CTT, a test score, which is called an observed score (X), is a combination of a true score (T) and an error score (E) as manifested in the following model: $X = T + E$. When investigating score reliability, the objective is to estimate the true (T) and error (E) scores. In the early 1970s, Cronbach and his colleagues introduced generalizability theory (G theory) as an alternative methodology that can provide more information about sources of variability in test scores (Cronbach, Gleser, Nanda, & Rajaratnam, 1972).

Brennan (2003) defines G theory as a measurement model that “provides an extensive conceptual framework and set of statistical machinery for quantifying and explaining the consistencies and inconsistencies in observed scores for objects of measurement” (p. 3). He argues that both CTT and analysis of variance (ANOVA) are the parents of G theory, but he cautions in another paper that G theory is not intended to replace CTT or limited only to traditional ANOVA (Brennan, 2000). Looking at the CTT model ($X = T + E$) and also the G theory definition, it is evident that G theory attempts to investigate the same issues addressed in CTT. However, CTT provides only one error term (E) and falls short of accounting for different sources of error. Making use of ANOVA, G theory can disentangle different sources of errors. In addition, the interaction between these sources of errors could also be reported in a generalizability analysis. For example, in a writing assessment context, a number of variables could confound test results, such as, tasks, raters, scoring rubrics, and so forth. In a CTT analysis, the relative contribution of these variables to a test score could not be quantified. Yet in a G theory analysis, the researcher can provide information about these variables and their relative contribution. Other advantages of G theory over CTT include providing a unified approach to assessing reliability for both norm-referenced and criterion-referenced situations, and also optimizing measurement for a specific testing context (see below).

Conceptually, Messick (1989) looks at G theory from two different standpoints: reliability and transfer. Generalizability as reliability refers to “the consistency of performance across the tasks, occasions, and raters of a particular assessment which might be quite limited in scope,” but generalizability as transfer refers “to the range of tasks that performance on the assessed tasks is predictive of” (Messick, 1996, p. 250). Perhaps generalizability as reliability is relatively clear since it has to do with the long-standing definition of reliability; however, generalizability as transfer might need more explanation. The context

Figure 1 The bridge analogy representing the chain of inferences in an assessment context (Chapelle, Enright, & Jamieson, 2008, p. 10). © 2008 by the Taylor & Francis Group

of speaking assessment provides a good example. A language teacher/tester judges a test taker's speaking ability based on a limited number of tasks, rather than all the possible speaking tasks in the target language use (TLU) domain (Bachman, 1990). However, we make inferences from the observed behavior (test tasks on the speaking test) about all the speaking tasks in the TLU domain. This process, as Kane, Crooks, and Cohen (1999) argue, depends on an interpretive argument that incorporates a chain of inferences. Kane et al. (1999) present a model that shows how this mechanism functions in an assessment context using the bridge analogy. In this model, there are three inferential bridges, each of which requires support for any assumptions or claims made by a test developer/user. As shown in Figure 1, the first of these three bridges is called evaluation and it is established when performance on a specific test is quantified in the form of an observed score. The second bridge focuses on generalization and refers to the inferences made about the expected performance of an examinee, statistically inferred from his or her observed score, across all the tasks in the universe of generalization (Kane et al., 1999). The final link or bridge is extrapolation and refers to the examinees' expected scores, being reflective of their actual ability and scores that they would have obtained in the target domain (Chapelle, Enright, & Jamieson, 2008). Clearly, any test design and administration decisions impact the quality of the interpretive argument and accordingly affect score generalizability. When we have a strong interpretive argument, we are confident to a great extent that a test score is an accurate representation of the ability of interest.

Basic Concepts in G Theory

This section addresses a number of G theory concepts that the reader might not be familiar with, including test facets, decision and generalizability studies, and more importantly the different generalizability indices.

One of the important aspects of G theory is the identification of sources of variation in test scores. Sources of variation are called "facets of measurement" in a G study and are identified by the researcher or test developer when conducting a generalizability analysis. For example, in a one-facet design, say items on a multiple-choice test, sources of variation include object of measurement (in G theory terminology, object of measurement refers to persons/test takers and is denoted as p) and the facet of interest "items" denoted as (i). In this design, the variance (denoted as σ^2) components are as follows: persons $\sigma^2(p)$, items $\sigma^2(i)$ and the interaction of persons and items $\sigma^2(pi)$. So, a test score variance $\sigma^2(Xpi)$ in this one-facet design is represented in the following formula:

$$\sigma^2(Xpi) = \sigma^2(p) + \sigma^2(i) + \sigma^2(pi)$$

In generalizability theory, the object of measurement variance $\sigma^2(p)$ is analogous to true score variance in CTT. The other variance components obtained from the different facets,

Figure 2 Variance components in a two-facet design

such as items (i), and raters (r), and also the interaction between these facets, may contribute to different types of error variance. These types of error variance in generalizability theory are comparable to the error term in CTT.

A researcher may decide to focus on more than one facet in an assessment context. For example, Gebril (2009) used a two-facet design looking at the impact of both tasks (t) and raters (r) on test scores. As shown in Figure 2, this design has seven variance components: person $\sigma^2(p)$; task $\sigma^2(t)$; rater $\sigma^2(r)$; the interaction of persons and tasks $\sigma^2(pt)$; the interaction of persons and raters $\sigma^2(pr)$; the interaction of tasks and raters $\sigma^2(tr)$; and the triple interaction of persons, tasks, and raters $\sigma^2(ptr)$. This could be summarized in the following formula:

$$\sigma^2(X_{ptr}) = \sigma^2(p) + \sigma^2(t) + \sigma^2(r) + \sigma^2(pt) + \sigma^2(pr) + \sigma^2(tr) + \sigma^2(ptr)$$

In G theory, we differentiate between two types of studies: generalizability (G) studies and decision (D) studies. While the main purpose of a G study is to estimate the different variance components, a D study makes use of the G study data to optimize the measurement for a certain decision-making purpose (Shavelson & Webb, 1991). In other words, the G study variance components are utilized in a D study to compute reliability indices under different conditions. In simple mathematical terms, a D study variance component signifies the ratio of the G study variance component and its respective sample size that is defined by the researcher. It is worth mentioning that the object of measurement variance is the only component that does not change in both studies since this value refers to the test taker's universe/true score. In the writing assessment example provided earlier, if two raters scored the essay, then a D study can use this information to estimate the changes in score reliability when using different numbers of raters. For example, we can decrease the number of raters from two to one (as shown below in the sample study) or increase it to three. Then, based on the analysis, these scenarios provide information for test developers about score reliability under different conditions, so that they can make decisions with regard to how many raters could be employed for a specific assessment context.

It is also important to distinguish between two types of decision-making situations in G theory: absolute and relative decisions. When absolute decisions are made, scores are compared to a set of criteria. In relative decisions, the relative standing or rank order of test takers is of interest. This distinction is of crucial importance since the components of measurement error are based on how the decision is defined (Brennan, 2001). Accordingly, the G theory indices used will depend on whether norm-referenced or criterion-referenced

interpretations are made based on test scores. Generally, there are four main indices obtained from a generalizability analysis: generalizability coefficient E_p^2 , phi coefficient Φ , absolute error variance $\sigma^2(\Delta)$, and relative error variance $\sigma^2(\delta)$. Both generalizability and phi coefficient are analogous to traditional reliability indices in CTT. A generalizability coefficient is used in situations where norm-referenced interpretations are of interest and it is computed based on relative error variance. On the other hand, a phi coefficient is used in criterion-referenced contexts and is computed based on absolute error variance. Absolute error variance is generally larger than relative error variance since it often includes all variance components except for the object of measurement variance $\sigma^2(p)$. Consequently, the phi coefficient will be smaller than the generalizability coefficient, given that both depend on error variance indices as mentioned earlier. For more information about how to interpret different score reliability indices, see Brennan (2003) and Johnson and Johnson (2010).

One final point that needs clarification in this section is the difference between univariate and multivariate generalizability. In univariate G theory, there is only one universe score for the object of measurement, while multiple universe scores could be obtained for the same object of measurement in multivariate generalizability theory (Brennan, 2003). That is why multivariate generalizability analysis is used when a test has a number of sections or subtests, and subsequently there is interest in investigating composite score reliability. Having one universe score does not permit univariate analysis to look into composite score reliability based on a number of test sections or subtests. Gebril's study presented in the following section explored two types of writing tasks: integrated and independent. Since Gebril (2009) analyzed the two tasks separately, univariate generalizability analysis was employed. Had independent and integrated tasks in this study been considered as subsections of the same test, multivariate generalizability analysis should have been used. For an example of a multivariate generalizability analysis, see Gebril (2010) and Brennan, Gao, and Colton (1995).

An Example of a G Theory Study

To better illustrate the concepts and terminology in G theory, the study of Gebril (2009) can serve as an example. This study investigated score reliability of both independent and integrated writing tasks. More specifically, the study attempted to answer the following questions regarding the use of integrated and independent tasks in an academic writing context:

- What percentage of the total score variance can be attributed to persons, tasks, and raters?
- What is the effect of successively increasing both the number of tasks and raters from one to four on score reliability?

To answer these questions, 115 English as a foreign language (EFL) students were asked to complete two independent and two reading-to-write tasks. These essays were holistically scored by three raters, who received training before scoring these tasks. Accordingly, the universe of admissible observations (UAO) for this study includes two facets: tasks (t) and raters (r). The study used a "fully crossed" design ($p \times t \times r$): The word "crossed" (denoted as x) means that all test takers responded to the same test tasks and these tasks were scored by the same raters. In some G theory studies, examinees take different tasks or the tasks are scored by different raters; these are called "nested" designs. For the purpose of this discussion, the focus will be on the independent tasks data only.

Table 1 Generalizability analysis for a writing test

<i>Sources of variation</i>	<i>VCS for G study</i> $n_t = 2 \text{ \& } n_r = 3$	<i>VCs for D study</i> $n_t = 2 \text{ \& } n_r = 1$	$n_t = 2 \text{ \& } n_r = 2$
$\sigma^2(p)$	0.149	0.149	0.149
$\sigma^2(t)$	0.000	0.000	0.000
$\sigma^2(r)$	0.000	0.000	0.000
$\sigma^2(pt)$	0.098	0.098	0.049
$\sigma^2(pr)$	0.015	0.015	0.008
$\sigma^2(tr)$	0.007	0.007	0.002
$\sigma^2(ptr)$	0.181	0.336	0.045
$\sigma^2(\delta)$ relative error		0.290	0.102
$\sigma^2(\Delta)$ absolute error		0.301	0.103
Ep^2 G coefficient		0.336	0.594
$\hat{\Phi}$ phi coefficients		0.331	0.590

Notes: n_t = number of tasks; n_r = number of raters

As pointed out earlier, the main purpose of a G study is to estimate the variance components (VC) for the different facets/effects using ANOVA procedures. As shown in Table 1, the VC for person (p) is (.149). This value refers to the person's expected mean score across all tasks and raters in the UAO (as mentioned earlier, this value is similar to true score variance in CTT). The estimated VC of task mean score is (.00), which indicates that all tasks in the UAO have the same difficulty level. The same value was obtained from the rater (r) facet, which shows rater consistency. As for the interaction VCs, these values refer to the relationship between the different test facets. For instance, there is a relatively large VC for the interaction of persons and tasks (pt), which suggests different rank ordering of persons across different tasks. The VC for the (pr) interaction has a relatively small value, which indicates that test takers were rank ordered similarly by different raters. Some of the VCs are very close to zero (some of them actually have a value of zero as shown in the task and rater VCs), suggesting that these components do not contribute to score variability. In conclusion, the total score variance in this design consists of seven different components shown in the first column of Table 1. These G study VCs are used to estimate the D study VCs, which will be explained next.

In this study a number of hypothetical scenarios were suggested to investigate the impact of increasing the number of tasks and raters on score reliability. The focus of this section will be only on two D studies where the number of raters was increased from one to two while keeping the number of tasks constant, as Table 1 shows. As mentioned earlier, there are four main indices obtained from a D study: generalizability coefficient, phi coefficient, absolute error variance, and relative error variance. In the following section, a description of how these indices vary with changes in the number of tasks and raters is presented. The D study results shown in Table 1 demonstrate substantial improvement in score reliability when moving from one rater ($n_r = 1$) to two raters ($n_r = 2$) while keeping the number of tasks constant ($n_t = 2$). For example, the generalizability coefficient jumped from .336 ($n_r = 1$) to .594 ($n_r = 2$). The same happened with the phi coefficient, which improved by a value of .26. So, as shown in this data set, it might be better to use two raters in this assessment context. To conclude, these scenarios provide invaluable information for testing programs when making test-related decisions.

G Theory Software

A number of computer programs are available for generalizability analysis, and most, if not all, of these programs are accessible as freeware. These different programs come with manuals that offer step-by-step guides for organizing and analyzing data.

The most widely used suite of programs was developed by Robert Brennan and is available for download from http://www.education.uiowa.edu/casma/computer_programs.htm. This package is called the GENOVA suite, and includes the following computer programs for generalizability theory analysis:

- *GENOVA*: This computer program is used for univariate generalizability analysis. It can run both G and D studies.
- *mGENOVA*: This computer program is used for conducting multivariate generalizability analysis with both G study and D study capabilities. It is worth mentioning that this program is used with a limited number of designs.
- *urGENOVA*: This program is used to estimate the variance components for unbalanced random effects (for more information about unbalanced designs, see Brennan, 2001). *urGENOVA* does not have D study capabilities.

EduG is another generalizability analysis program with a simpler layout. It can be downloaded from <http://www.irdp.ch/edumetrie/englishprogram.htm>. This program is ideal for those who have basic understanding of generalizability theory and need a user-friendly interface. For more information about EduG, see Cardinet, Johnson, and Pini (2010).

Conclusions

G theory is a powerful tool for estimating the consistencies and inconsistencies in test score and for also providing test developers with scenarios that can help them make informed decisions related to test development and administration. G theory could be used effectively in investigating the relative contribution of different facets to test precision. For example, the rater facet is always an issue in language testing, especially in language performance assessment. Testing programs have to make decisions with regard to the number of raters needed for a certain test. For instance, the decision whether to use two or three raters hinges on the score dependability of data obtained from a D study based on a scenario including two raters and another one including three. The task facet is another variable of interest in test design. G theory can also provide information about the impact of increasing or decreasing the number of test tasks. Accordingly, the final number of test tasks is identified based on the precision indices obtained from a generalizability analysis. Testing programs can also make use of the powerful tools of G theory in their test validation studies in order to optimize the measurement precision of their exams. The Test of English as a Foreign Language (TOEFL) program is a good example of how generalizability analysis is used in test validation. Educational Testing Services (ETS) conducted a number of studies to investigate the score reliability of the TOEFL test using G theory (e.g., Lee & Kantor, 2005). From the previous discussion, it is clear that G theory has wide applications in language test development given its powerful tools and the rich data obtained from a generalizability analysis. The currently available generalizability software has made the relatively complicated G theory calculations easier, and hopefully these new computer programs will encourage more language testers and teachers to use G theory in test development and validation.

Generative Grammar

SATU MANNINEN

Generative grammar is an approach to linguistics which is usually associated with Noam Chomsky and his followers, starting in the mid-1950s and continuing to the present day. Generative grammar has had a number of different names through its development. These include transformational grammar (TG), transformational-generative grammar (TGG), standard theory (ST), extended standard theory (EST), principles and parameters model (P&P), government and binding theory (GB), and the minimalist program (MP). For an overview of the development, see, for example, Ouhalla (1994, 1999); Newmeyer (1996); Cook and Newson (2007); Freidin (2007). A number of alternative approaches have branched off the “Chomskyan” mainline. These include lexical-functional grammar (LFG, see e.g., Bresnan, 2001; Dalrymple, 2001; Carnie, 2002), generalized phrase structure grammar (GPSG, see e.g., Gazdar et al., 1985), and its successor head-driven phrase structure grammar (HPSG, see e.g., Pollard & Sag, 1994; Carnie, 2002; Levine & Meurers, 2006), and optimality theory (OT, see e.g., Prince & Smolensky, 2004). What often distinguishes these alternative approaches from the “Chomskyan” mainline is their stand on how many linguistic levels there are, and how these levels should be related to each other (i.e., via *transformations* or through some other formal mechanism).

Generative grammar, in its various forms, assumes that all linguistic phenomena can be subject to formal analyses, and that they can, in fact, be best explained in such terms. Generative grammar is therefore in opposition to the functional family of linguistic theories, which assumes that language is essentially a means of communication between humans, and that all linguistic phenomena should therefore be analyzed in terms of their communicative function.

Within Chomskyan traditions, the grammar of a language is thought to consist of several separate components; what these components are and what they should be called has varied a lot over the years. I will start with an overview of the processes and terminology used within the (early) minimalist traditions, and then go back in time and discuss some key concepts (for overviews, see e.g., Chomsky, 1993, 1995, 2000; Radford, 1997, 2004; Ouhalla, 1999; Carnie, 2002; Adger, 2003; Hornstein et al., 2005; for accessible overviews within preminimalist traditions, see e.g., Radford, 1988; Haegeman, 1994; Ouhalla, 1994). One of the key components is the lexicon, which can be thought of as a list of lexical items in a language and their idiosyncratic properties. In order to form a given expression in a language, such as the sentence *The dog ate the bone* in English, a speaker must first select a set of lexical items known as the “numeration” or the “lexical array” from the lexicon. These lexical items are then combined, through a series of operations, in the syntactic/computational component of the grammar. This process is known as the *derivation*. The task of the syntactic/computational component is to form expressions which can serve as input to the two interpretive components of grammar. The phonological component maps the “sound aspects” of the expression into a phonetic form representation, while the semantic component maps the “meaning aspects” of the expression into a semantic or logical form representation. The task of the phonetic form and semantic/logical form representations is to *interface* with the language-external systems of speech and thought. We can think of these representations informally as “instructions” about sound and meaning to the systems of speech and thought: these “instructions” tell the speaker-hearer

2 GENERATIVE GRAMMAR

Figure 1 Components of grammar

something about (for example) the pronunciation and the intended interpretation of the expression. We can represent the separate components of grammar as shown in Figure 1; the block arrows represent the points where the system interfaces with the language-external systems of speech and thought.

The idea that the syntactic/computational component is able to produce all and only the well-formed expressions of a language has been part of generative grammar from its early days. According to Chomsky (1965, p. 8) a generative grammar is then “simply a system of rules that in some explicit and well-defined way assigns structural descriptions to sentences.”

A well-formed expression is one that can be assigned a structural description by the grammar; in minimalist terminology, this means that the expression can be “interpreted” by the language-external systems of speech and thought. An ill-formed expression is, in turn, one that cannot be “interpreted” by the language-external systems. The idea that an expression can be “interpreted” is related to the notion of *convergence* (e.g., Chomsky, 2000, p. 95). If an expression is *legible* at an interface level (i.e., if it consists solely of material that can be “understood” by the language-external system in question) the derivation is said to *converge* at that level. If the derivation fails to converge, it is said to *crash*. This happens, for example, when an expression that is intended to interface with the speech systems still contains “instructions” about meaning and interpretation. Because such “instructions” are incomprehensible to the speech systems, the derivation crashes and results in ill-formedness (i.e., in an expression that cannot be assigned a structural description).

Innateness and Universal Grammar

The syntactic/computational component of grammar is able to produce an infinite number of well-formed expressions in a language, by applying, often recursively, a finite set of formal grammatical rules. These rules are subconscious, in the sense that they are part of the mind/brain of an ideal speaker-hearer. According to Chomsky (2000, pp. 90–1) there is

a faculty of language FL, a component of the human mind dedicated to language. . . . FL can be regarded as a “language organ,” in the informal sense in which visual system, the immune system, and the circulatory system are commonly described as organs of the body.

One of the central—and most controversial—ideas in generative grammar is that the language faculty has an initial state which is *genetically endowed*. This means that human children are genetically programmed to learn language. The initial state of the language faculty is known as *universal grammar*; it may be characterized informally as the rules or principles that are common (i.e., universal) to all human languages. Experience of a particular language (such as the actual words, phrases, and sentences that children hear native speakers use in different speech situations around them) serves as the input to each

child's language faculty incorporating universal grammar, and provides the child with a means for developing the grammar of that particular language. The idea is, then, that certain aspects of grammar are determined by universal rules or principles which are genetically endowed and innate, but that experience (i.e., exposure to primary linguistic data from a particular language) determines if the child will grow up speaking English, Swedish, Japanese, or something else. For more detailed accounts, see, for example, Chomsky (1965, 1986, 1995, 2004, 2005, 2007); Chomsky, Fitch, and Hauser (2002).

Haegeman (1994, p. 14) and Carnie (2002, p. 23) discuss some simple examples of how the rules or principles provided by universal grammar can result in differences between individual languages. It is widely known that sentences in natural languages contain elements that are traditionally labeled subjects and objects. These elements need not appear in the same order in all languages, however. In English, illustrated in (1) below, objects normally follow the lexical verb in linear order, whereas in Japanese, illustrated in (2), they precede it (examples from Haegeman, 1994, p. 14):

(1) John hit Mary.

(2) John-ga Mary-o but-ta.
 John-particle Mary-particle hit-past
 'John hit Mary'

The pattern in (1)–(2) is an instance of what is known as the *head parameter*; this parameter allows the grammarian to capture the fact that in some languages, heads systematically precede their complements in linear order, whereas in others, they follow them. In a head-first language like English, this parameter predicts that the verb should come before the object in linear order, and that the language is likely to have prepositions instead of postpositions, whereas in a head-final language like Japanese, the parameter predicts that the verb should come after the object, and that the language is likely to have postpositions instead of prepositions. All grammatical variation between individual languages should be reducible to such parameters; the task of universal grammar is to specify the binary choice of values for each parameter.

Competence and Performance

In the 1960s, Chomsky proposed a distinction between *competence*, that is, native speakers' implicit knowledge of their language, and *performance*, that is, how native speakers put their implicit knowledge of language to use (how they use the language in different speech situations). The grammarian's task was to provide a description of native-speaker competence: to describe what native speakers really know when they know their language, so they are able to distinguish the *well-formed* expressions in their language from the *ill-formed* expressions. Providing a description of performance was necessarily outside the scope of inquiry (and it still is); this disinterest in language use is one of the reasons why generative grammar has been so heavily criticized especially within the functional family of linguistic theories.

The distinction between competence and performance is closely intertwined with the notion of descriptive and explanatory adequacy. A grammar is said to be *descriptively adequate* if it is able to "correctly describe the intrinsic competence of the idealized native speaker" (Chomsky, 1965, p. 24). A grammar that is *explanatorily adequate* is, in addition, able to provide some insight into the underlying linguistic structures in the human brain (Chomsky, 1965, pp. 25–6). So, instead of merely listing sets of universal properties of

natural language grammars, a system that is explanatorily adequate must be able to explain how children learning a specific natural language can succeed in selecting a descriptively adequate grammar for their language, on the basis of a limited amount of primary linguistic data. In recent years, attention has also been given to the question of why natural language grammars should have the properties that they have in the first place (e.g., Chomsky, 2004, 2005, 2007).

I-Language and E-Language

In the 1980s, Chomsky proposed a distinction between I(nternalized)-language and E(xternalized)-language, which is similar but not identical to the competence versus performance distinction. An E-language approach to linguistic theorizing treats language as an observable pattern of human action or behavior. Language, as the object of study, is externalized, in the sense that it is “understood independently of the properties of the mind/brain” (Chomsky 1986, p. 19). In contrast, an I-language approach treats language as a mental object; language is “some element of the mind of the person who knows the language, acquired by the learner, and used by the speaker-hearer” (Chomsky 1986, p. 22). Because language, in the sense of I-language, is a property of the human brain, the study of language must consequently be seen as a branch of (cognitive) psychology.

Levels of Representation and Transformations

Most “Chomskyan” approaches to language assume that the linguistic system has different *levels of representation* encoding systematic information about linguistic expressions. The earlier versions of generative grammar distinguish between two levels: *deep structure* and *surface structure*. The former is seen as the locus of semantic interpretation, while the latter corresponds to the actual (phonetic) form of the expression. This means that ambiguous expressions, such as *Flying planes can be dangerous* (from Chomsky, 1965, p. 21), must have different deep structures, but share the same surface structure form. Deep structures are mapped onto surface structures via series of *transformations*. A transformation is a formal linguistic operation that allows the two levels of representation to be placed in correspondence. We can represent the system as shown in Figure 2; the surface structure corresponds (roughly) to the phonetic/semantic form representations in Figure 1, and the transformations correspond to the syntactic/computational component.

One of the best-known transformations is *movement*. A simple example is given in (3) and (4).

- (3) The dog is barking.
- (4) Is the dog barking?

Figure 2 Levels of representation in early generative grammar

The *yes/no question* in (4) has been formed from an underlying declarative sentence in (3), by moving the auxiliary verb *is* across the sentence subject (i.e., the noun phrase *the dog*). The moving element can be either a head (head movement) or a phrase (phrasal movement). Examples of phrasal movement include *wh*-movement, exemplified in (6), passivization (8), and topicalization (10); the moved phrases are in italics. Movement leaves behind a *trace* in the original position; this is indicated by an italicized *t*:

- (5) Is the dog eating the bone?
- (6) *What* is the dog eating *t*?

- (7) The dog ate the bone.
- (8) *The bone* was eaten *t* (by the dog).

- (9) The dog ate the bone.
- (10) *The bone*, the dog ate *t* (. . . but the shoe, it left alone).

In generative traditions, the derivation of an expression is often represented in the form of a tree diagram; one of the best-known theories of phrase structure is *X'-theory* (X-bar theory), which aims to bring out the common properties of different syntactic constituents, such as NPs, VPs, and so on. See, for example, Chomsky (1970); Jackendoff (1977); Radford (1988); Haegeman (1994).

In the 1980s, standard government and binding theory posited four levels of representation: D(eep)-structure, S(urface)-structure, phonetic form, and logical form. The levels are again related via series of transformations, as shown in Figure 3.

The difference between government and binding theory and the system illustrated in Figure 1 is that each level of representation can be illustrated in the form of a (different) tree diagram, and is subject to different requirements. D-structure is the starting point of the derivation: it is also the level where an expression's semantic properties correspond to its grammatical properties. This means that semantic subjects correspond to D-structure subjects, and semantic objects to D-structure objects. S-structure is the point where the derivation splits into two parts: the branch that leads to phonetic form allows the expression to interface with the language-external system of speech, and the branch that leads to logical form is the locus of semantic interpretation. It also allows the expression to interface with the language-external system of thought. Characteristic of government and

Figure 3 Levels of representation in government and binding theory

binding theory is that movement operations can be either *overt* (i.e., mappings from D-structure to S-structure) or *covert* (i.e., mappings from S-structure to logical form). An example of covert movement is so-called quantifier raising, which is taken to explain sentences such as (11) with scope ambiguity (i.e., the fact that they can have two readings):

- (11) Everyone loves someone.
 ‘For every person in the world, there is some other person who s/he loves’
 ‘There is one specific person who everyone else in the world loves’

In government and binding theory, the different readings assigned to sentences such as (11) are treated as a result of the quantifiers having moved to different structural positions; as this movement has taken place after S-structure, it is not reflected in the overt (phonetic) form of the expression (May, 1985; Haegeman, 1994).

The minimalist approaches to language restrict the levels of representation to those that are required by *virtual conceptual necessity*—namely, to those that interface with the language-external systems of speech and thought. As the task of grammar is to ensure that a well-formed expression is assigned both a form and an interpretation, the levels of phonetic form and semantic/logical form are seen as being independently motivated on conceptual grounds. The derivation proceeds by merging material that has been selected from the numeration or lexical array, or by moving material from a structure that has been created earlier. Instead of X'-theory, minimalist approaches make use of the simple *bare phrase structure* theory. (Chomsky, 1995, 2000, 2001; Carnie, 2002; Adger, 2003; Radford, 2004; Hornstein et al., 2005).

Many recent minimalist approaches argue for what is known as *multiple spell-out*. This means that there is no *single* point in the derivation of an expression where the material that is relevant only for phonetic or for semantic interpretation is sent off to the phonetic form or the semantic/logical form branch. Instead, material can be sent off to these branches several times in the course of the derivation of an expression. The idea is that expressions are built *cyclically*, bit by bit, and when a specific point in derivation is reached, the material can be sent off to be interpreted. These bits are known as *phases* (Chomsky, 2001, 2006; Radford, 2004).

Nontransformationalist Approaches

There exist a number of alternative versions of generative grammar; these include lexical-functional grammar (LFG; e.g., Bresnan, 2001; Dalrymple, 2001; Carnie, 2002), generalized phrase structure grammar (GPSG; e.g., Gazdar et al., 1985), and its successor head-driven phrase structure grammar (HPSG; e.g., Pollard & Sag, 1994; Carnie, 2002; Levine & Meurers, 2006), and optimality theory (OT; e.g., Prince & Smolensky, 2004). LFG is characterized as being constraint-based, unification-based, and nonderivational, in the sense that structures are not seen as having been derived from other structures, via operations such as movement. Although LFG makes use of a number of different levels of representation, each of these is seen as modeling a different dimension of grammatical substance. They are not related via transformations; instead, they are associated by principles of functional correspondence.

HPSG is similar to LFG in being constraint-based, unification-based, and nonderivational. However, unlike LFG, which makes use of multiple levels of representation, HPSG is *monostratal*, in that it assumes only one level of representation. This level is encoded in a complex sign structure, and it contains information about phonology, syntax, and semantic interpretation all at the same time. This means that in HPSG grammars, a lot of information must necessarily be stored in lexical entries.

OT is a system where each input (such as a set of words) is thought to give rise to a set of outputs (e.g., a set of different sentences). Each output is evaluated with respect to a hierarchy of constraints, and the one with the least violations of these constraints is selected as the optimal candidate. Since the mid-1990s, OT approaches have been successfully employed especially in (morpho-)phonological research.

Generative Second Language Phonology

FRED R. ECKMAN

Introduction

Generative second language (L2) phonology attempts to characterize the underlying mental system used by adult language learners to produce and perceive L2 pronunciation patterns. This entry covers the historical context and the objectives of research programs in generative L2 phonology, describing some of the field's major findings over the past several decades.

Early Approaches to L2 Phonology

One of the earliest, best-known, and most straightforward proposals for explaining second language phonological patterns is the contrastive analysis hypothesis (CAH), which dates from the middle of the last century (Lado, 1957). Work on L2 phonology from the CAH perspective claimed that structural differences between the native language (NL) and target language (TL) were paramount in accounting for L2 utterances. The goal of these studies was to explain L2 learning difficulty. During this period, a phonological analysis consisted of a description of the phonemes of a language along with the distribution of their allophones. Phonemes are the sound units that function to distinguish the words and morphemes in a language, whereas allophones are sounds that are variants of phonemes in the language, and therefore do not function to distinguish words. Within the CAH framework, L2 pronunciation errors were attributed to differences among the phonemes and their distribution within the respective NL and TL, often leading to the L2 learner transferring phonemes from the NL to the TL.

In the decades following the postulation of the CAH, some studies supported it. However, many others ran counter to the hypothesis, and led ultimately to its demise. On balance, research within the CAH paradigm showed that, whereas NL influence played a role in explaining some aspects of L2 pronunciation patterns, the influence of the NL could not explain all of the facts. It became clear, therefore, that other principles were necessary to explain L2 learning difficulty. Since that time, research in L2 acquisition has sought to address this need. Attempts toward this end include proposals pertaining to the similarities between the NL and TL, facts about the relationship between production and perception, and principles of markedness.

Similarity between the NL and TL is a key concept in two important models focusing on the role of L2 perception, the speech learning model (SLM) developed by Flege (1995), and the perceptual assimilation model (PAM), proposed by Best (1995). The concept of "equivalence classification" is invoked in the work of Flege (1986, 1987), especially within his SLM, in which he hypothesizes that TL sounds that are "equivalent" or "similar" to NL sounds are difficult to acquire because the learner perceives these TL sounds as being the same as the NL sounds. When TL segments are perceived as equivalent to those of

the NL, the learner does not establish a new phonetic category, that is, a set of variant pronunciations considered by the speaker to be the same sound, for the TL sounds. However, learners do set up new phonetic categories for TL sounds that are perceived as different from those of the NL. This, in turn, enables the learners to progress in acquiring these new phonetic categories. A similar approach to perception is taken within the PAM, in which non-native segments are perceived according to their similarities and differences relative to the native sounds.

Another principle introduced into SLA theory to help address problems with the CAH is typological markedness. The idea behind markedness is that binary contrasts or oppositions between certain linguistic elements (e.g., voiced and voiceless consonants—consonants articulated with the presence or absence, respectively, of vocal cord vibration; or open and closed syllables—syllables that, respectively, end in a vowel or in at least one consonant) are not simply polar opposites. Instead, one member of the opposition is considered to be privileged in that it occurs more widely, both across and within languages. This term has taken on different definitions within several distinct approaches to linguistics (Battistella, 1990). In L2 phonology, markedness, as defined in (1), was incorporated into the CAH as a measure of relative difficulty, forming the markedness differential hypothesis (MDH) (Eckman, 1977).

(1) *Typological markedness*

A structure X is typologically marked relative to another structure Y if every language that has X also has Y, but every language that has Y does not necessarily have X.

The MDH predicted that a given TL structure would be more difficult if that structure were different from the corresponding NL representation, and if it were also more marked than the NL structure. Whereas the CAH attempted to explain L2 learning difficulty only on the basis of differences between the NL and TL, the claim behind the MDH is that NL–TL differences are necessary, but not sufficient, for such an explanation. Therefore the MDH incorporated the concept of typological markedness as a measure of relative difficulty. Over the last three decades numerous studies have addressed the claims of the MDH, showing that typological markedness is a reliable predictor of difficulty, that there are cases where the directionality of difficulty between the NL and TL involved in a language-contact situation follows the predictions of the MDH, and that the relative degree of difficulty corresponds to the relative degree of markedness (Anderson, 1987; de Jong, Silbert, & Park, 2009).

The final proposal that we will discuss is the similarity differential rate hypothesis (SDRH), formulated by Major and Kim (1996). The SDRH reprises the idea from Wode (1976) and from Flege's SLM (1995) that dissimilar sounds may be easier than sounds that are similar to those in the NL. The SDRH claims that dissimilar structures are acquired more quickly than similar structures, with markedness as a mediating factor. According to this hypothesis, "rate of acquisition" is the basis for explaining many L2 pronunciation errors, not difficulty, as is stated in both the CAH and the MDH.

In summary, we have identified several proposals addressing some of the perceived shortcomings of the CAH. Thus, conventional wisdom within the field of L2 phonology is that, although the learner's NL has a role to play in explaining certain aspects of learning difficulty, NL influence is by no means sufficient to account for all L2 pronunciation patterns. Moreover, all the frameworks discussed in this section continue to be invoked by researchers to address questions and problems in L2 phonology.

More Recent Approaches to L2 Phonology: Interlanguage

Interlanguage (IL), a term coined by Selinker (1972), refers to the mental system representing the L2 learner's version of the TL. This mental system is used to produce and understand utterances of the TL. The IL grammar of the L2 learner must be different in at least some respects from both the NL grammar and the TL grammar. This is true, on the one hand, because the L2 utterances produced by the learner are different from that learner's NL utterances, and, on the other hand, because the L2 utterances of the learner are also distinct from those produced by native speakers of the TL. On this view, second language acquisition becomes the construction of a mental grammar, the interlanguage. And although the acquisition of this IL grammar may be based in part on structures transferred from the NL, and in part on input from the TL, the IL is to some extent independent of both the NL and TL, because at least some L2 patterns are not part of either the NL or TL.

An example of this kind of IL pattern in L2 phonology was reported in Altenberg and Vago (1983). The authors found that native speakers of Hungarian learning English exhibited an L2 pattern motivating a rule of word-final devoicing, that is, a pattern in which words that normally end in a voiced consonant are pronounced with the corresponding voiceless consonant. This conclusion is intriguing, as neither the grammar of the NL nor the grammar of the TL has a word-final devoicing rule, because both languages have a voice contrast in word-final position. Thus, the devoicing rule in the ILs of the Hungarian learners of English is independent of both the NL and TL in that it is not attributable either to NL transfer or TL input. This rule, however, is attested in other languages of the world, including Catalan, German, Polish, and Russian.

To summarize, the concept of interlanguage led directly to the possibility that L2 patterns could emerge that were independent of both the NL and TL. This possibility raised the question of whether IL grammars are in fact similar in important respects to L1 grammars.

Constraints on IL Grammars

With the postulation of the notion of interlanguage, the objective of SLA theory, and by inclusion, generative L2 phonology, changed from explaining learning difficulty in L2 acquisition to addressing the question of why IL grammars are the way they are. The response that the research programs of this era have given to this question is along these lines: "SLA is the way it is because IL grammars are the way they are; and IL grammars are as they are because they are constrained by general linguistic principles." In the case of L2 generative phonology, the constraints are principles of phonological theory, and within this context, it is also possible for explanations to hark back to the role of the learner's NL. Thus, a number of proposals hypothesized that various linguistic principles interacted with the NL grammar to explain L2 phonological patterns. Approaches to L2 phonology differed on which kinds of theoretical principles the investigators proposed as constraining IL grammars, and on the extent to which the learner's NL interacted with these constructs. We now turn our discussion to the kind of principles that were proposed as constraining IL grammars.

The development of phonological theory during this period led to a number of general principles and concepts from phonology, including distinctive features—articulatory properties of sounds; the types of rules postulated; underlying representations—representations of words within a grammar in terms of phonemes; and derivations—a mapping of underlying representations onto pronunciations. All were seen as a way of accounting for L2 utterances. As nonlinear proposals made their way into phonological theory, prosodic hierarchies (Zampini, 1997), metrical grids (Archibald, 1995, 1997), and feature geometry

(Brown, 1998, 2000) were also employed as explanatory principles in L2 phonology. These can be characterized as aspects of describing or representing words and morphemes in terms of hierarchies of phonological properties as well as a linear string of sounds. An additional source for constraints was linguistic universals, interpreted in the broadest sense, including typological generalizations and principles of universal grammar (UG). Typological generalizations are empirical statements that divide languages into different types based on the presence or absence of certain structures, such as voiced contrasts, plurals, definite articles, and various sentence types. UG is postulated to be an innate, cognitive device consisting of a set of principles that children employ for internalizing a grammar of their native language. More recently, as many theoretical phonologists have turned from rule-driven grammars to constraint-based analyses, studies have focused on L2 pronunciation in terms of optimality theory (OT). In OT, grammars consist of a set of ranked constraints instead of a set of rules, and constraint rankings and re-rankings in the learner's interlanguage determine the time course of acquisition (Hancin-Bhatt & Bhatt, 1997; Broselow, Chen, & Wang, 1998; Hancin-Bhatt, 2000, 2008). During this era, one of the important recurring themes in L2 phonology has been the reporting and proposed explanation of L2 phonological patterns that are not directly attributable either to the learner's NL or to the TL, but may be attested in the phonologies of other languages. Indeed, it is this kind of evidence that purports to show the fundamental properties involved in the acquisition of L2 phonology. Given this context, we now turn our discussion to some of the proposals for how L2 interlanguage phonologies are constrained.

The first example to be discussed involves the employment of prosodic hierarchies and metrical grids to account for the stress patterns of L2 learners. A prosodic hierarchy is a structural representation of the phonological domains relevant to the application of rules, with the phonetic segment being the smallest domain, the syllable the next larger, the prosodic foot consisting of a pair of syllables the next larger, and so on, with the utterance being the largest and most inclusive domain. A metrical grid is a structural hierarchy of the syllables and prosodic feet of a given utterance from which properties of stress can be predicted. Such constructs have been invoked (e.g., Archibald, 1993, 1995, 1997) to account for the acquisition of L2 stress patterns. Archibald found that the NL had a role to play in IL stress patterns in that L2 learners transferred some, or all, of their NL metrical grid into the IL grammar, but that the NL principles that applied to these grids may operate differently in the IL grammar than they do in the NL or in the TL.

Other kinds of phonological constructs have also been put forth as constraints on IL grammars; these include aspects of feature geometry and underspecification, along with principles governing the well-formedness of syllables. We first take up the use of features and then turn to syllables.

Brown (1998, 2000) proposed feature geometry and underspecification as explanatory devices for L2 pronunciation patterns. Feature geometry is a system of representing segments in which phonological features are not unordered bundles of properties, but are instead structured hierarchically so that some features are dependent on others. Underspecification is a system for representing the underlying representations of segments that takes advantage of the fact that some properties of sounds are predictable, that is, they constitute a regularity, on the basis of other properties. These predictable aspects of sounds are redundant for making contrasts, and are not represented underlyingly. All features are completely specified only when the segments are realized phonetically. Assuming that feature geometry and underspecification are principles that constrain IL phonologies, just as they constrain L1 grammars, Brown employed them in her analysis of the acquisition of several English contrasts by speakers of Japanese, Korean, and Mandarin.

Studies involving principles of syllable structure as a constraint on IL grammars have been carried out, for the most part, using NLs which are much more restrictive than English

in the kinds of syllables they allow. Sato (1984) conducted one such study of two Vietnamese-speaking brothers, aged ten and twelve; she elicited utterances exclusively through spontaneous conversations. Although Vietnamese allows only clusters consisting of a consonant and a glide in onsets, that is, clusters containing a consonant followed by a [j] or a [w] sound, and permits only singleton codas, Sato's data contained numerous tokens of syllable-initial and syllable-final consonant clusters. More recently, Hansen (2004) carried out a year-long study of two Vietnamese learners of English, mapping the development of onsets and codas as a function of several linguistic and contextual factors. Some longitudinal studies have raised the question of whether the development of L2 syllable structure is linear. Both Hansen (2001) and Abrahamsson (2003) concluded that coda development over time was U-shaped rather than linear.

We now focus our attention on the proposal that linguistic universals act as constraints on IL grammars, and then conclude this section with a discussion of the framework of OT. Within this context, there are two schools of thought on linguistic universals, namely typological generalizations and UG, and we begin our discussion with the latter.

A parameter of UG is a constraint on grammars that specifies how grammars can differ from each other with respect to a given structure. An early study that utilized a parameter as an explanatory principle was Broselow and Finer (1991), which invoked the minimal sonority distance (MSD) parameter to explain the performance of Korean and Japanese learners of English on the production of onset clusters.

The MSD parameter uses the sonority index (SI), from Selkirk (1982), which assigns a numerical value to relevant segment types according to the segment's sonority. In general, sonority can be defined in terms of how open the mouth is when the sound is articulated, with stop sounds being the least sonorous and vowels being the most sonorous, and with other sound types occurring in between stops and vowels. The greater the sonority of the segment, the greater the value assigned by the SI. As shown in (2), sonority increases from left to right on the SI scale, and the corresponding values assigned are shown in (3).

- (2) *Sonority index (Selkirk, 1982)*
Stops < Fricatives < Nasals < Liquids < Glides

(3) <i>Segment class</i>	<i>Value</i>
Stops	1
Fricatives	2
Nasals	3
Liquids	4
Glides	5

The idea is that the MSD parameter characterizes the systematic variation found in the kinds of syllable onsets allowed crosslinguistically, specifying for any given language the minimal numerical difference that must exist between the segment classes for any complex onset type to be allowed by the language in question. If the value calculated for any given cluster is equal to or greater than the value specified by the MSD for that language, then the onset cluster is allowed in that language; if the resulting value is less than that number, the cluster is disallowed.

The most interesting point in the Broselow and Finer (1991) study was the finding that their subjects neither simply transferred the value of the MSD parameter of the NL into the IL, nor evidenced TL-like values of this parameter. Rather, the subjects produced IL patterns that were somewhere in between the NL and TL settings, providing another instance in which interlanguage grammars obey general principles of phonological theory.

An approach to L2 phonology that invoked generalizations from the other school of

universals, typological markedness, is the structural conformity hypothesis (SCH) (Eckman 1991), stated as in (4).

- (4) *The structural conformity hypothesis* (Eckman, 1991, p. 24)

The universal generalizations that hold for primary languages hold also for interlanguages.

Consistent with the point made in the above section on interlanguage, the strongest kind of support for the SCH is an L2 pattern in which the structures adhere to universal principles, but the patterns in question are not directly derivable from either the NL or the TL. This type of evidence has been adduced in a number of studies, including Altenberg and Vago (1983), Eckman (1991), Carlisle (1998), and Eckman and Iverson (1994), among others.

Having described a number of proposals for how IL phonologies are constrained by general principles and linguistic universals, we conclude this section with a discussion of the framework of OT as it has been applied to the explanation of L2 phonologies.

The most significant difference between a grammar within OT and a grammar within other phonological approaches is how well-formedness is described. In rule-based grammars, a well-formed representation is characterized by constructing a set of rules, that is, a grammar, which, if adhered to, will yield grammatical utterances. Grammatical deviance is described by showing that ungrammatical representations violate at least one of the principles of the grammar. Within OT, on the other hand, grammars consist of a universal set of constraints instead of rules. The constraints represent criteria for well-formedness. The assumption is that no language can satisfy all of these criteria; therefore, the constraints of the grammar can be violated, and conflicts among constraints are resolved by ranking them for any given language. Thus, within the framework of OT, grammars of particular languages result from different rankings of the universal constraints. Any ranking of these constraints should yield a grammar of some language, and any grammar of a language should conform to one of the possible rankings of the constraints.

In recent years several important studies on L2 phonology have been carried out within an OT framework. Hancin-Bhatt and Bhatt (1997), for instance, reprised and extended the Broselow and Finer (1991) study of the acquisition of English complex onsets by native speakers of Japanese and Korean. The authors concluded that OT gives a superior account of the data because it characterizes the differences between Japanese and Spanish solely in terms of the ranking of identical constraints, making it clear that the language-particular differences were the basis for the pronunciation errors. In another OT analysis, Broselow et al. (1998) illustrated how the simplification strategies used to modify English codas by native speakers of Mandarin could be explained as “the emergence of the unmarked,” which is one of the ways that OT grammars can represent an L2 pattern that is independent of both the NL and TL.

Conclusion

To summarize, the study of L2 pronunciation patterns can be divided historically into earlier studies considering the patterns only in terms of the native and target languages, and those investigating L2 phonology from the standpoint of the mental system of the L2 learner, the interlanguage grammar.

Genesee, Fred

DONNA CHRISTIAN AND AILEEN BACH

Fred Genesee (1948–) is a researcher and professor of psychology whose work has shaped the fields of bilingual and second language (L2) acquisition and education. For decades he has taken a comprehensive approach to the investigation of language acquisition and learning, from instruction, including the effectiveness and suitability of immersion programs for all students, to theoretical advances in bilingual and L2 acquisition, to methodological issues in assessing communicative competence, to literacy development in second language learners. He is well known for reaching across professional boundaries, engaging parents, teachers, administrators, policy makers, and researchers in discussing issues in multilingual and multicultural communities.

Fred Genesee, a native of Canada, completed his undergraduate degree in Honors Psychology at the University of Western Ontario in 1969, and went on to complete a Masters and PhD in Psychology at McGill University in 1970 and 1974, advised by the distinguished psychologists Wallace E. Lambert and G. Richard Tucker. After several years as head of research for the Protestant School Board of Greater Montreal, Quebec, working with French immersion programs, in 1978, he became a faculty member in the Psychology Department at McGill University, where he continues to work today. Over the course of his career, Genesee also spent time at several other universities, including the University of Hawaii at Manoa (1984–6) as visiting professor in the Department of English as a second language, and the University of California, Davis (1997–8), where he served as director of the Division of Education.

Genesee's career began at a critical and highly contentious time for language planning in Montreal as French became increasingly prominent and important in Montreal and throughout the province of Quebec. Many English-speaking families were seeking educational options that would enhance their children's competence in French so that they could better adapt to this changing linguistic landscape. French immersion was created to respond to their needs. This model of bilingual education, devised by McGill University psychologists Wallace Lambert and G. Richard Tucker, with Wilder Penfield at the Montreal Neurological Institute, and a group of English-speaking Montreal parents in the mid-1960s, involved "immersing" English-speaking students in French for 100% of their instruction in kindergarten to grade 2. Genesee collaborated with Lambert and colleagues for decades, studying and working with Canadian immersion programs, contributing to the body of research on bilingual and L2 acquisition, and supporting the spread of the immersion approach to the United States and elsewhere.

Research on these pioneering immersion programs led Genesee and his colleagues to tackle a variety of topics, including the nature and effectiveness of different types of immersion education, the sociocultural, affective, and cognitive outcomes of participation in immersion programs, and the suitability of immersion for students with different learner characteristics (see Genesee, 1987, for a review of this early work). In all of his work, Genesee has consistently invited discussion and collaboration among parents, teachers, and school administrators, as well as policy makers and researchers from a diversity of fields. As a result, he is respected and admired by members of all of those groups.

Genesee's research has contributed greatly to the field's evolving understanding of basic constructs in bilingualism and second language acquisition. For example, an important question his research has addressed is whether the languages of children who acquire two languages simultaneously are represented in the brain separately or as one entity. In the case of young bilinguals, many have postulated that code switching, or using two different languages in a single sentence or conversation, is evidence that children do not distinguish between their two languages, and that their languages are represented in a single system in the brain until they learn to distinguish between the two (e.g., Volterra & Taeschner, 1978). In contrast, Genesee (1989) showed that young bilingual children are sensitive to the different contexts in which to use each of their languages, arguing against the view that young bilingual children go through an initial stage when their two languages are fused or indistinguishable. In addition, research by Comeau, Genesee, and Lapaquette (2003) showed that young bilingual children can systematically adapt their rate of code switching to that of their interlocutors, suggesting that code switching is actually a reflection of bilingual children's sociolinguistic competence.

With regard to L2 learning, a key question has been whether learners acquiring an L2 later in life are able to achieve native-level proficiency, given the claims of the critical period hypothesis, which states that there is an optimal developmental period for learning a language, beyond which native proficiency in a language cannot be obtained (Lenneberg, 1967). Genesee, along with his colleague Lydia White, addressed a common methodological flaw in studies that claimed to demonstrate that late L2 learners are unable to attain native proficiency, pointing out that they had only demonstrated a *tendency* for this to be the case (White & Genesee, 1996). They argued that in order to determine whether late L2 learners have the neurocognitive capacity to access the same psychological mechanism that early L2 speakers use to achieve native-level proficiency, late L2 learners who demonstrate native-like proficiency should be investigated. He continues to explore issues of the brain and second language learning with his graduate students and colleagues at McGill (e.g., White, Genesee, & Steinhauer, 2009).

Genesee has also conducted pioneering research on language acquisition in diverse and special populations, including international adoptees (e.g., Gauthier & Genesee, 2011), children with language learning disorders (Paradis, Crago, Genesee, & Rice, 2003), students considered at-risk for educational failure, and very young children (from infants to pre-school age) (Genesee, 2009). Through his research, he has pushed the boundaries of inquiry on basic notions of bilingualism and the populations whose language accomplishments merit our attention.

Genesee has made strong contributions not only to language education practice and research in Canada, but also in the United States and around the world. Building on his groundbreaking work on French immersion and bilingualism in Canada, he joined research teams working on similar issues elsewhere and collaborated on publications that document multilingual education in diverse settings (Cenoz & Genesee, 1998; Christian & Genesee, 2001). In the United States, as immersion programs gained attention, he became a resource and colleague for those seeking to implement and conduct research on immersion, and helped to build the emerging field of dual language education (with its emphasis on bilingualism through school-based programs that provide literacy and content area instruction to all students through two languages). He also focused on issues in the education of English-language learners more broadly and worked extensively on research, technical assistance for schools, and materials development for teachers. His influence has spanned program alternatives, instructional approaches, special education, and literacy for the English learner population (Genesee & Lindholm-Leary, in press). In 2001, he was appointed to the National Literacy Panel on Minority Language Children and Youth, tasked by the US Department of Education to synthesize the current state of knowledge on the topic

(e.g., Genesee & Geva, 2006). In addition to having written a number of enlightening books for the research field, such as *Learning Through Two Languages* (Genesee, 1987) and *Educating English Language Learners* (Genesee, Lindholm-Leary, Saunders, & Christian, 2006), Genesee has also coauthored a number of practitioner-oriented handbooks, such as *Dual Language Instruction* (Cloud, Genesee, & Hamayan, 2000), *Dual Language Development and Disorders* (Genesee, Paradis, & Crago, 2004), and *Literacy Instruction for English Language Learners* (Cloud, Genesee, & Hamayan, 2009) which have served as valuable resources for practitioners in the field. This broad range of achievements demonstrates Genesee's lifelong commitment to seeking new knowledge and applying it to improving the lives of individuals.

The fields in which he works have recognized Genesee's achievements on countless occasions. In 2004, for example, he was awarded the Canadian Psychological Association Award for Distinguished Contributions to Public or Community Service in Canada, and in 2008, he received the Promoting Bilingualism award from 2Way CAFE, the branch of the California Association for Bilingual Education that focuses on two-way immersion education. His research has also been honored, as with the 1990 Paul Pimsleur Award for Research in Foreign Language Education from the American Council on the Teaching of Foreign Languages. He has served on the boards of numerous professional organizations, including the International Association for the Study of Child Language, the American Association for Applied Linguistics, and the Center for Applied Linguistics. He also served as President of Teachers of English to Speakers of Other Languages (TESOL) from 1994 to 1995.

Genesee's contributions to the field of bilingual and second language acquisition and education are both broad in scope and grounded in a strong commitment to influencing practice. He has been instrumental in the progress of dual language education in North America and beyond, as a researcher of immersion and other bilingual and second language education programs. He has also contributed greatly to current theoretical debates in the field, challenging psycholinguistic theories of bilingual and second language acquisition to reflect accurately the bilingual and second language learner. He nurtures contacts across traditional academic boundaries, and communicates his research findings in ways that are accessible to diverse audiences including families, practitioners, theorists, and policy makers. His vision for multilingual education has enriched both the field of applied linguistics and the lives of language learners around the world.

Genre and Discourse Analysis in Language for Specific Purposes

KEN HYLAND

Language for specific purposes (LSP) refers to a distinctive approach to language education that focuses on the particular linguistic features, discourse practices, and communicative skills used by target groups. Its success depends on accurately identifying what these features and practices are so they can be taught to students, and this has been greatly assisted since the late 1980s by the emergence of genre analysis. Genre analysis has become established as one of the most popular and productive frameworks for the study of specialized communication in academic, professional, and institutional contexts. Essentially, the approach is used to describe texts within textual and social contexts, rejecting the idea that individual texts should be treated in isolation from either their use or other texts. This entry will offer an overview of the importance of genre and discourse analysis in this area of research and pedagogy.

Discourse and Genre Analysis

Discourse analysis is a collection of methods for studying language in action, looking at texts in relation to the social contexts in which they are used, but this broad definition has been interpreted in various ways across the social sciences. This is because language is an irreducible part of social life, and connected to almost everything we do. Discourse analysis, in fact, spreads between two poles, giving more or less emphasis to concrete texts or to institutional social practices, but generally tending to focus on language phenomena that occur above the level of the sentence. Genre analysis is a more specific form of discourse analysis that focuses on any element of recurrent language use, including grammar and lexis, that is relevant to the analyst's interests. Genres are the recurrent uses of more-or-less conventionalized forms through which individuals develop relationships, establish communities, and get things done using language. As a result, genre analysis sees texts as representative of wider rhetorical practices and so has the potential to offer descriptions and explanations of both texts and the communities that use them.

Genre analysts set out to offer descriptions of "typified acts of communication" based on the form and purposes of texts. Fundamentally, genres are kinds of broad rhetorical templates that writers draw on to respond to repeated situations; users see certain language choices as representing effective ways of getting things done in familiar contexts. Genre analysis is therefore grounded in the assumption that the features of a similar group of texts depend on the social context of their creation and use, and that those features can be described in a way that relates a text to others like it and to the choices and constraints acting on text producers. This is the very stuff of communication. O'Sullivan, Hartley, Saunders, Montgomery, and Fiske (1994, p. 128), for instance, argue that "genres are agents of ideological closure—they limit the meaning-potential of a given text," while writers can rely on readers already having some knowledge and expectations about the conventions of a genre. We know immediately, for example, whether a text is an essay, a joke, or a recipe, but we can also recognize innovation, irony, and creativity. Genres can thus be

seen as a kind of tacit contract between writers and readers, influencing the behavior of text producers and the expectations of receivers.

While approaches to genre differ considerably in the emphasis they give to text or context, the research methods they employ, and the types of pedagogies they encourage, text-analytic varieties have had most impact in LSP contexts. These approaches are influenced by Halliday's (1994) view of language as a system of choices that link texts to particular contexts through patterns of lexico-grammatical and rhetorical features (Christie & Martin, 1997), and by Swales's (1990) observation that these recurrent choices are closely related to the work of particular discourse communities whose members share broad social purposes. These purposes are a key element of the context of a text and the rationale of a genre; they help to shape the ways it is structured and the choices of content and style it makes available. The following sections discuss the aspects of language usually studied, the relationship between genre and context (both social and textual), and the application of research to pedagogy.

Genre Structures and Features

Perhaps the most fruitful line of research in LSP has been to focus on *genre as text*, with the aim of exploring the lexico-grammatical and discursive patterns of particular genres to identify their recognizable structural identity, or what Bhatia (1999, p. 22) calls "generic integrity." Analyzing this kind of patterning has yielded useful information about the ways texts are constructed and the rhetorical contexts in which such patterns are used, as well as providing valuable input for genre-based teaching.

Some of this research has followed the move-analysis work pioneered by Swales (1990), which seeks to identify the recognizable stages of particular institutional genres and the constraints on typical move sequences. Moves are the typical rhetorical steps that writers or speakers use to develop their social purposes, and recent work on academic genres has produced descriptions of the results sections in research articles (Bruce, 2009), dissertation acknowledgments (Hyland, 2004c), and grant proposals (Connor, 2000). In professional contexts, research has explored the structures of genres in direct mail letters (Upton, 2002) and in management and legal cases (Lung, 2008).

While analyzing schematic structures has proved an invaluable way of looking at texts, analysts are increasingly aware of the dangers of oversimplifying by assuming blocks of texts to be mono-functional and ignoring writers' complex purposes and "private intentions" (Bhatia, 1999). There is also the problem raised by Crookes (1986) of validating analyses to ensure they are not simply products of the analyst's intuitions. Transitions from one move to another in a text are, of course, always motivated outside the text as writers respond to their social context, but analysts have not always been convincingly able to identify the ways these shifts are explicitly signaled by lexico-grammatical patterning.

Research has therefore tended to move more toward examining clusters of register, style, lexis, and other features that often distinguish particular genres. One feature of academic genres to receive attention is writers' use of *evaluative that* constructions in articles and dissertations (Hyland & Tse, 2005). This is a structure that allows a writer to thematize evaluative meanings by presenting a complement clause following *that* (as in *We believe that this is an interesting construction*). Other recent studies have looked at circumstance adverbials in student presentations (Zareva, 2009), interactive features of undergraduate lectures (Morell, 2004), and the common four-word collocations, or lexical bundles, in student dissertations (Hyland, 2008). In other domains, research has identified genre characteristics such as the use of conjunctive cohesion in EU documents (Trebits, 2009) and metadiscourse markers in professional e-mails (Jensen, 2009). A feature of much recent

work has been to investigate how persuasion in various genres is accomplished not only through the ways ideas are presented, but also by the construction of an appropriate authorial self and the negotiation of participant relationships.

Genre and Community

The importance of genre to LSP studies results from the growing body of evidence that professional and academic discourses represent a variety of specific literacies, so that what counts as convincing argument, appropriate tone, persuasive interaction, and so on is managed for a particular audience (Hyland, 2004a). More specifically, researchers have become sensitive to the ways genres are written and responded to by individuals acting in concert with others. This community-based orientation to literacy draws attention to the idea that we communicate as members of social groups, each with its own norms, categorizations, sets of conventions, and ways of doing things.

Essentially, members of a community usually have little difficulty in recognizing similarities in the texts they use frequently, and they are able to draw on their repeated experiences with such texts to read, understand, and perhaps write them relatively easily. This is, in part, because writing is a practice based on expectations. The process of writing involves creating a text that the writer assumes the reader will recognize and expect, and the process of reading involves drawing on assumptions about what the writer is trying to do. Writer and reader assemble sense from a text by anticipating what the other is likely to do by making connections to prior texts.

Genre analysis therefore reveals the ways that genres reflect and construct the communities that use them, as Swales observes:

In-group abbreviations, acronyms, argots, and other special terms flourish and multiply; beyond that, these discourse communities evolve their own conventions and traditions for such diverse verbal activities as running meetings, producing reports, and publicizing their activities. These recurrent classes of communicative events are the genres that orchestrate verbal life. These genres link the past and the present, and so balance forces for tradition and innovation. They structure the roles of individuals within wider frameworks, and further assist those individuals with the actualization of their communicative plans and purposes. (1998, p. 20)

The idea that people acquire, use, and modify texts while acting as members of academic, occupational, or social groups offers a powerful way of describing communities and understanding the communication needs of students in professional and academic contexts.

A recent development in genre studies has been the growth of ethnographic approaches as a way of accessing features of the context and of the processes of production that may explain particular aspects of genres. Research into situated academic discourse, such as J. Swales's "textography" (1998) and A. Johns's "students as researchers" work (1997), indicates how ethnographic methods, such as observation of physical sites of genre activity and interviews with individuals who read or write a genre, can provide access to these communities and their genre use.

Genre Constellations

Another aspect of context lies in the ways that texts relate to other texts, forming "constellations" with neighboring genres (Swales, 2004). An important aspect of such constellations is that we almost never find genres in isolation. A useful concept here is that of "genre

sets,” referring to the part of the entire genre constellation that a particular individual or group engages in, either productively or receptively (Devitt, 1991). Textbooks, lab reports, and lectures, for instance, may be key genres for many science students, while discussion postings and online tutorials are genres more familiar to distance-learning students on teaching English to speakers of other languages (TESOL) programs. We can also approach genre constellations through “genre chains,” a term that refers to the way spoken and written texts cluster together in a given social activity. Thus genres sometimes follow each other in a predictable chronological order, such as a job application that involves a step-wise procedure through job advertisement, curriculum vitae, application letter, interview, and so on.

Moving beyond the immediate context to the wider “context of culture,” genres can be seen as institutional social practices. From this perspective, genres are loosely arrayed in a *network* as each interacts with, draws on, and responds to another in a particular setting. This view refers to Bakhtin’s (1986) concept of intertextuality and the fact that every utterance reacts to other utterances in that domain. While this totality is constantly changing, analysis can help show how text users are linked into a network of prior texts according to their group membership. These interconnections can be characterized as both intertextual and interdiscursive. “Interdiscursivity” concerns the use of elements in a text that carry institutional and social meanings from other discourses, reflecting the conventions, values, and practices of neighboring discourses.

One example of how an institutional genre is linked into a web of interdiscursivity is the undergraduate syllabus (Afros & Schryer, 2009), which is linked not only to other course documents and texts but also to wider understandings of the institution and the discipline itself. As the authors point out:

The syllabus reveals that the social creation of knowledge taking place in the course draws on lectures, textbooks, and other in-class and out-of-class learning/teaching activities as much as on the ongoing discussion in the academic field, adult education, university policies, and many other texts and communities. Instructors utilize the syllabus not only to manifest their membership in multiple discourse communities, but also to socialize students into (at least, some of) them. (p. 231)

Thus, the syllabus highlights the interdependences between the classroom, research, and institutional genres.

Genre Pedagogies

The findings produced by genre studies have had a major impact on LSP teaching. This is because genre descriptions ground teaching in research and support learners through an explicit understanding of how target texts are structured and the reasons they are written as they are. The potential advantages of genre-based instruction for writing can be summarized as follows (Hyland, 2004b):

Explicit	Makes clear what is to be learned to facilitate the acquisition of writing skills.
Systematic	Provides a coherent framework for focusing on both language and contexts.
Needs-based	Ensures that course objectives and content are derived from target needs.
Supportive	Gives teachers a central role in scaffolding students’ learning and creativity.

Empowering	Provides access to the patterns and possibilities of variation in valued texts.
Critical	Gives students the resources to understand and challenge valued discourses.
Consciousness raising	Increases teachers' awareness of texts and helps them confidently advise students on writing.

While these characteristics are not unique to genre pedagogy, no other approach seeks to realize them all.

LSP practitioners employ genre pedagogies as a means of emphasizing what is to be learned, organizing instruction around the genres that learners need and the social contexts in which they will operate (Hyland, 2004b). This typically involves adopting a scaffolded pedagogy to guide learners toward control of a genre based on whole texts selected in relation to learner needs. Based on sociocultural learning theory (Vygotsky, 1978), scaffolding is a metaphor of learning that refers to the supportive behaviors by which an expert can help a novice learner to gradually achieve higher, independent levels of performance. In LSP classrooms it involves active and sustained support by a teacher who models appropriate strategies for meeting particular purposes, guides students in their use of the strategies, and provides a meaningful and relevant context for using the strategies.

Texts and tasks are therefore selected according to learners' needs and genres are modeled explicitly to provide learners with something to aim for, namely an understanding of what readers are likely to expect. One approach widely used in Australia is the teaching-learning cycle (e.g., Feez, 1998), which helps inform the planning of classroom activities by showing the process of learning a genre as a series of linked stages. Here the teacher provides initial explicit knowledge and guided practice, moves to sharing responsibility for developing texts, and gradually withdraws support until the learner can work alone. The key stages of the cycle are

- setting the context—to reveal genre purposes and the settings in which it is commonly used,
- modeling—analyzing representative samples of the genre to identify its stages and key features and the variations that are possible,
- joint construction—guided, teacher-supported practice in the genre through tasks that focus on particular stages or functions of the text,
- independent construction—independent writing by students monitored by the teacher,
- comparing—relating what has been learned to other genres and contexts to understand how genres are designed to achieve particular social purposes.

Each of these stages seeks to achieve a different purpose, and so is associated with different types of classroom activities and teacher-learner roles (Hyland, 2004b, pp. 130–40).

Critiques

Genre approaches have not been uncritically adopted in LSP classrooms. Situated-learning theorists (e.g., Dias & Pare, 2000), for example, argue that writing is always part of the goals and occasions that bring it about and that it cannot be learned in the inauthentic context of the classroom. Such a view, however, ignores the fact that second language (L2) students are often at a considerable disadvantage in such unfamiliar naturalistic settings and that genre-based teaching can cut short the long processes of situated acquisition. Critical theorists have also attacked genre teaching, for accommodating learners both to existing modes of practice and to the values and ideologies of the dominant culture that

the valued genres embody (e.g., Benesch, 2001). Genre proponents, however, contend that this argument can be leveled at almost all teaching approaches, and that learning about genres does not preclude critique but, in fact, provides a necessary basis for critical engagement with cultural and textual practices.

Finally, genre teachers have had to defend themselves against process adherents and the charge that genre instruction inhibits writers' self-expression and straitjackets creativity through conformity and prescriptivism (e.g., Dixon, 1987). Obviously the dangers of a static, decontextualized pedagogy are very real if teachers fail to acknowledge variation and apply what Freedman (1994, p. 46) calls "a recipe theory of genre." But there is nothing *inherently* prescriptive in a genre approach. There is no reason why providing students with an understanding of discourse should be any more prescriptive than, say, providing them with a description of a clause or the parts of a sentence. The fact is that genres *do* have a constraining power that inevitably limits the originality of individual writers. Selecting a particular genre implies the use of certain patterns, but this does not *dictate* the way we write: it enables us to make choices and facilitates expression. The ability to create meaning is only made possible by the possibility of alternatives. By ensuring these options are available to students we give them the opportunity to make such choices, and for many LSP learners this awareness of regularity and structure is both facilitating and reassuring.

Conclusions

LSP instruction seeks to help demystify prestigious forms of discourse, unlock students' creative and expressive abilities, and facilitate their access to greater life chances. To accomplish these goals teachers require a systematic means of describing texts and of making their students' control over them more achievable. In short, a well-formulated theory of how language works in human interaction has become an urgent necessity in the field of teaching languages for specific purposes. Genre pedagogies are a major response to this need, providing teachers with a way of understanding how writing is shaped by individuals making language choices to achieve purposes in social contexts.

Genre-Based Language Teaching

CHRISTINE M. TARDY

The basic principle of genre-based language teaching is that awareness of the forms, purposes, and social contexts of texts will aid in writing development. In applied linguistics, the term “genre” is used to refer to forms of communication that have become conventionalized through repeated use. Genres are created by social groups, such as academic or professional communities, to carry out various goals of the group. Common genres in academic disciplinary contexts include, for example, research articles or book reviews, while common genres in business contexts may include memos or project proposals. Learning such genres involves learning the socially preferred “ways of doing” within the community. Because key modes of communication within communities are often *generic*, learning to engage in these genres receptively and productively can be essential to success as a group member. The goal of genre-based language teaching is to facilitate this process.

Beyond this general shared goal, approaches to genre-based language teaching vary somewhat. One prominent approach to genre-based teaching draws on principles of systemic-functional linguistics (SFL). This approach was developed largely out of early work by James Martin, Francis Christie, and Joan Rothery, who proposed genre-based pedagogy as an alternative to the process approach and its emphasis on student centeredness and personal genres, arguing that process pedagogy further marginalized students from non-dominant socioeconomic and linguistic groups. Because of these scholars’ connection with the University of Sydney, those associated with this approach are at times referred to in the USA as “the Sydney School.” The approach was developed to respond to the needs of students in K–12 school settings. Despite its continued affiliation with Australian-based scholarship, SFL-oriented genre-based teaching is implemented around the world in a range of contexts, including K–12 literacy education, foreign language education, and vocational language education. The notion of genres within the SFL orientation is theoretically grounded in Hallidayan functional linguistics (Halliday, 1994) and are defined as social processes, the intersection of social patterning and textual patterning (Cope & Kalantzis, 1993). Common categories of genres in this view include, for instance, narrative, description, report, discussion, and recount. SFL-oriented genre-based teaching aims to help learners explicitly identify the textual features of such genres so that they can more effectively produce them on their own. Early examples of genre-based teaching in this approach were based largely on a cycle of discovery, which included modeling of the genre, joint construction of a generic text, and independent construction of a generic text. While this particular cycle may not be followed in all instances of today’s SFL-influenced genre-based teaching approaches, they generally share the principle of helping students draw explicit connections between language structure, purpose, and social power.

A second prominent approach to genre-based language teaching is associated with English for specific purposes (ESP) and has developed largely out of early work by John Swales and Tony Dudley-Evans. Recognizing that texts vary both linguistically and rhetorically in different disciplinary communities, Swales developed a method of analyzing the structural components of a text according to each component’s rhetorical purpose or function (Swales, 1981, 1990). He referred to these components as “rhetorical moves” and the analysis of these components as “move analysis.” Drawing on his own experience as an ESP instructor, particularly with advanced academic writers, Swales argued that a

conscious awareness of these moves—as well as other characteristic features of the target genre—can facilitate a mastery of the genre. Genre-based pedagogy in ESP, then, is characterized by awareness-raising activities in which students are themselves investigators of the target genre. Such activities commonly include analysis of linguistic features, such as common lexicogrammatical structures, and rhetorical structures, such as moves or perhaps practices for citing sources. As theories of genre have evolved to increasingly recognize the extent to which genres are rooted in the changing practices and values of their users, genre-based teaching in ESP has also begun to incorporate the social nature of genres to a greater extent. In addition to analyzing a genre's linguistic and rhetorical features, students in genre-based classrooms may now also investigate the procedures through which a genre is carried out within a particular social group, the structures of power within the social group, or the network of genres that work together to carry out group activities. Such tasks aim to help students build insight into the ways in which texts themselves shape and are shaped by the users and their socially preferred “ways of doing.”

Closely related to ESP genre-based teaching—sometimes considered a branch of it—is the socioliterate approach to genre teaching described by Ann Johns (1997). While this approach shares the theoretical orientation of ESP and an emphasis on awareness raising, it is sensitive to the needs of undergraduate university students, who contend with different writing contexts than writers in highly specialized academic or professional contexts. The goal of this approach is for students to continually revise and build their theories of genre and to apply their genre knowledge to analysis and critique of the texts that they encounter (Johns, 2002). Like other approaches to genre-based teaching, attention is given to students' development of a meta-awareness of and metalanguage for discussing texts and contexts.

An additional orientation to genre-based teaching can be found among North American scholars of university writing instruction, focused implicitly on first language writing development (e.g., Devitt, Bawarshi, & Reiff, 2003). Though scholars in this area have recognized and drawn upon some applied linguistics scholarship, the orientation is more firmly grounded in the discipline of rhetoric. As such, the goal of genre study within this orientation is often to understand the social context through the text; in contrast, SFL and ESP genre study generally aims to understand the text through the situational context (Flowerdew, 2002). Emphasizing rhetorical context over form, this approach to genre-based pedagogy engages students in analysis and critique of common school genres. Students may, for example, analyze course syllabi or argument papers with the aim of understanding the rhetorical “scenes” in which such writing takes place (Devitt, Reiff, & Bawarshi, 2004). Students can then apply their complex understanding of writing contexts to making informed decisions about their own writing.

The small number of studies of genre-based language teaching have found support for the approach in several contexts. For instance, studies have found that genre-based teaching can benefit students' motivation, metalanguage, and development of rhetorical knowledge; the presence of sample texts and modeling practices also appears to have benefits for learners (Tardy, 2006). Nevertheless, genre-based pedagogy has not been without its critics. There has been considerable debate, for example, as to whether professional genres, as socially embedded practices, can or should be taught in the classroom (see Freedman, 1993a, 1993b). Similarly, some have expressed concern that teaching genres would imply that they are static in nature, when in fact they shift over time and across social contexts (Freedman & Medway, 1994); this criticism would seem less applicable to pedagogical approaches in which students learn to analyze genres rather than learn static features of genres. Finally, it has been argued that genre-based pedagogy serves to maintain current power structures by encouraging students to conform to—rather than challenge—existing norms (Pennycook, 1997).

The theoretical principles of genre-based language teaching are grounded most explicitly in theories of nonliterary genre. Though many contemporary adaptations of these approaches draw on rich interdisciplinary genre theories, early iterations were heavily influenced by more specific theoretical definitions. Early SFL-oriented approaches, for instance, were shaped by Martin's definition of genre as "staged, goal-oriented process" (Martin, 1993, p. 142), while ESP-oriented approaches have been perhaps most influenced by Swales's (1990) definition of genres as goal-oriented communicative events situated within a social group. Rhetoric-oriented approaches have often drawn heavily on Miller's (1984) definition of genre as a social action. More recently, genre scholars have drawn on theoretical perspectives across orientations, sharing a similar focus on the socially situated and intertextual nature of genres.

In writing instruction, genre-based language teaching has been associated with the postprocess movement. In contrast to the individualist orientation of process-based approaches, genre-based teaching emphasizes a social perspective, seeing written texts and writing practices as context-dependent (Hyland 2003). More implicitly, genre-based language teaching approaches draw on the cognitive principle of noticing, which posits that conscious attention to particular forms can facilitate learning of those forms (Schmidt, 1990). Hyland (2007) also observes that such awareness raising benefits teachers by increasing their confidence in advising students on genre writing.

German for Specific Purposes

HEIDI BYRNES

Background and Scholarly Context

German for specific purposes (GSP) refers to courses that explicitly connect learning the German language in the classroom with using it in the world of work and the professions, whether that work is course-concurrent (e.g., internships and practica), part of study abroad (again often including internships), or the student's future career. In the United States, the focus of this contribution, GSP courses are typically offered in colleges and universities; in Europe, especially in Germany, they are also taught in proprietary schools, in institutes associated with universities or technical universities, in trade schools, and by the Goethe Institut, a government-funded organization that advances the presence of German language and cultural activities around the world.

GSP is a response to contemporary social and professional needs, especially in the globalized environment of commerce, trade, banking, and business, as well as in manufacturing, engineering, and the sciences. Those changed needs reflect changed student interests with regard to learning a language (Rarick, 2009). At the same time a GSP presence also constitutes an internally directed critique inasmuch as it uncovers divergent philosophies about the educational values, goals, and responsibilities of higher education foreign-language (FL) departments and their programs. It is therefore small wonder that the established faculty often interprets these developments by sharply juxtaposing a valued traditional liberal arts and humanities orientation against the undesirable "instrumental" quality of a GSP component. What is more surprising is that such characterizations persist even in times of dramatically shrinking enrollments, particularly in upper-level classes.

Seen in this fashion, GSP is part of a larger shift in higher education toward an expertise orientation. How that is played out is almost entirely driven by local conditions. Particularly successful realizations of GSP can comprise an entire degree program, such as the five-year dual degree German and Engineering program at the University of Rhode Island (Grandin, Einbeck, & von Reinhart, 1992; Rarick, 2009). More common are course-based offerings in Business German, where some are well integrated into the existing program and constitute minors or recognized tracks, others remain stand-alone offerings (for different manifestations, see, e.g., the programs at the University of South Carolina, Clemson University, Eastern Michigan University, Georgetown University, Georgia Tech, Michigan State University, Purdue University, the University of North Carolina-Charlotte, the University of South Carolina, Texas Tech, and the Thunderbird graduate school at the University of Arizona).

GSP offerings tend to be seen as opportunistic and lacking a coherent educational vision. Structurally they often reside outside academic departments in "institutes" and "centers," the most frequent of these being federally funded Centers for International Business Education (CIBERS). A different optic would recognize their unusually close and advantageous collaboration with professional schools. Not surprisingly, their theoretical grounding has been questioned because they often lack a coherent linking of language and content (e.g., Hoecherl-Alden, 2000; Weigert, 2004; Rinner & Weigert, 2006). It is therefore questionable whether one can speak of a new discipline as Cothran and Gramberg (2000) do, all the

2 GERMAN FOR SPECIFIC PURPOSES

more so as the last two decades show advances primarily in terms of better program delivery through increased options for instructional materials, enhanced collaboration among programs (including resource sharing), and more widespread and more varied use of technology (see Hager, 2007). In short, many of the themes sounded earlier on for language for specific purposes (LSP) (see Uber Grosse & Voght, 1991; also the updated discussion in Lafford, 2011) continue to characterize the contemporary discussion in GSP (Wiggers, 2010) while conceptually oriented advances that might engender public debate and lead to generalizable insights and substantive changes are very nearly absent.

GSP programs are best understood in the context of developments in FL studies in the United States that began in the mid to late 1980s. While they have some affinity to LSP considerations in other languages, especially the highly developed and dominant programs in English for specific purposes (ESP) (Swales, 2000), dynamics in FL teaching have been much more influential. Five directions have been particularly noteworthy. First, the proficiency movement, the US version of emphasizing communicative abilities and performance *in* a language rather than knowledge *about* a language, rejected the earlier focus on grammar, downplayed the importance of literary texts, demanded “authenticity” of activities in the classroom and instructional materials, privileged “learner-centered” instruction that considered students’ interests and motivations, and, through the ACTFL oral proficiency interview, became outcomes-oriented and aware of the need for internal and external accountability. Second, the “language across the curriculum” (LAC) movement (Adams, 1996) sought to include content from disciplines other than FL literary-cultural studies. Third, “content-based instruction” (CBI) was yet another way of overcoming a continuing emphasis on grammatical form while neglecting college-level content (Krueger & Ryan, 1993). Fourth, task-based instruction foregrounded meaningful interactive language use in order to accomplish real-world objectives on the assumption that this would foster language development (Bygate, Skehan, & Swain, 2001). Fifth and finally, the recent European innovation of “content and language integrated learning” (CLIL) (see, e.g., <http://www.goethe.de/ges/spa/dos/ifs/en2747558.htm>), combines subject matter content with language instruction, mostly English at the secondary level. Taken together, these movements provided a favorable context in which GSP could become a presence in the larger field of German-language instruction.

GSP received its first extended treatments in publications in the early 1990s. The fall of the Berlin Wall in 1989 and Germany’s subsequent unification considerably heightened interest in the study of German at the very moment when enrollments at many institutions in the US had begun to fall, in some cases even to the point of endangering the existence of entire degree programs and departments (Rarick, 2009). More important, these stunning political developments in Germany attracted students from outside the humanities disciplines. Retaining them beyond existing language requirements demanded that connections between German and their fields of study be made in a way that would be more explicit, more deliberate, and more goals- and outcomes-oriented than earlier CBI and LAC efforts had been.

How that was accomplished in US colleges and universities is extraordinarily situated, if not to say idiosyncratic. Grandin, Einbeck, and von Reinhart (1992) mention six factors for the planning and implementation phase of a GSP program: (a) accommodating a multitude of career-oriented interests; (b) attending to different motivations for language learning in line with different interests, including quite unabashedly instrumental motivations that a liberal arts orientation tends to shun as unattractive; (c) respecting different attitudes of language learning as a means to an end; (d) relating the different purposes and anticipated contexts for language use to different linguistic needs on the part of the learners (e.g., content-specific vocabulary, progression of syntactic structures, various types

of discourse, register); (e) carefully selecting pedagogical approaches in light of different student backgrounds and skills; and (f) respecting different learning and cognitive styles.

Virtues and Drawbacks of GSP Programs

The unmistakable practice and learner orientation of the previous list is at once virtue and drawback. The following are key manifestations of both dynamics in the life of GSP programs.

Program and Degree Status

Many GSP programs have a tenuous status by comparison with the well established academic FL departments. GSP offerings have typically appeared as a result of the extraordinary personal initiative of one or a very few faculty members who argued for the viability, even necessity of offering GSP courses in order to respond to student interests. Often, they hardly qualify for the term “program.” Whether GSP courses are offered within the FL department or reside within a “center,” whether they count toward the major or minor or are electives, whether they are taught regularly or so infrequently as to get little traction in an institution—all of these factors greatly depend on local conditions.

Administrative Support

Similarly unstable is the administrative support for GSP, at the departmental level and above. Assuming that budgetary support springs from perceived intellectual-academic value, GSP programs often fight an uphill battle, trapped in an unfortunate dichotomy between a negatively positioned instrumental versus a positively valued liberal arts interpretation. This is so although GSP programs regularly affirm their intellectual link to the humanities and find ways of realizing it programmatically (e.g., Grandin, Einbeck, & von Reinhart, 1992; Hoecherl-Alden, 2000). The meeting point for both positions is the much-invoked term of “culture” (see below).

Even so, GSP initiatives inherently seek interdisciplinary connections beyond the inner circle of humanities disciplines, a move that frequently is cheered in the abstract but frowned upon in concrete cases, not least because of the ever-present concern of being reduced to purely service status, with no discernible intellectual center or educational merit. Unfortunately, that possibility can be unwittingly abetted by faculty and administrators in the other units. A particularly plausible route for making interdisciplinary connections and attaining a recognized programmatic status and more stable administrative support is via CIBERs, often themselves grant-funded environments and linked to business or professional schools. Other linkages under the umbrella of GSP involve similarly burdened interschool and interdisciplinary ventures.

Upper-level administrators tend to be much in favor of the educational thrust of GSP, in part because they see it as a welcome response to student interest and one way to counteract the unsustainable low-enrollment advanced literary-cultural studies courses within German programs. But even that does not readily translate into academic-administrative long-term support for GSP, since such a shift involves risk-taking with regard to an institution’s internal and external educational identity.

Faculty Availability

Without exception, the GSP literature refers to faculty resources as a critical dilemma for the field. Typically educated in literary-cultural studies, faculties feel ill prepared—and therefore unwilling—to handle the at times highly complex subject matter in the social

4 GERMAN FOR SPECIFIC PURPOSES

sciences (e.g., business) and the hard sciences and engineering. Aware of the considerable time investment in needed GSP materials creation they understandably shy away, all the more so as the faculty reward system continues to privilege traditional publishing activities. As a result, contingent faculty or even graduate students often sustain the effort as best they can (Grair, 2010), further strengthening the detrimental fault lines and hierarchies of FL departments.

Faculty Expertise and Competence

Beyond faculty availability lie issues of faculty competence and faculty development. GSP publications readily acknowledge that faculties who lack an educational background in technical, scientific, or business fields might be considered (and consider themselves to be) unqualified to teach such courses. In reply they emphasize that the role of faculties in GSP courses is less one of conveying the details of disciplinary content and more one of facilitating overall communicative abilities in German, starting at the beginning of instruction and gradually moving toward upper performance levels (von Reinhart, 2001; Rarick, 2009). Such a pedagogy would also allow students to be the “subject matter experts,” a shift in power relationships that is seen to be favorable in communicatively oriented classrooms. The dilemma of faculty expertise is likely to remain as long as a GSP orientation has no presence or status in graduate education, the setting for the education of the future faculty.

Need for Curricular Thinking

The orientation of GSP toward advanced, professional ability levels is difficult to conceptualize, much less realize programmatically for two overriding reasons. First, integrated curricula spanning the full four-year undergraduate sequence and thereby capable of sustained continued language development are notoriously rare in college FL departments, including German departments. Second, inasmuch as GSP offerings often come about because of tenuous, accommodating, even defensive postures, they are often even less capable of developing a principled conceptual framework for a comprehensive GSP curriculum.

Under those conditions curriculum is what is deemed to have been “successful” elsewhere, with “workability” often being elevated to “model” status for initiatives in one’s own institutional context. Beyond the URI program (Rarick, 2009), only the GSP courses within the explicitly genre-oriented and task-based curriculum within the German Department at Georgetown University show principled curricular thinking and, with that status, are fully integrated into the department’s degree requirements and its efforts of moving students toward advanced forms of multiple literacies. Otherwise, programs debate what should be included in a “GSP curriculum” (Borst & Schenck, 2007), affirm the central role of “culture” (Hoecherl-Alden, 2000), and suggest diverse content areas. Not surprisingly the EU and Germany’s position within it receive repeated mention (Weigert, 2004; Rinner & Weigert, 2006; Hedderich, 2009).

The Central Role of Study Abroad

GSP programs are unique for their heavy emphasis on study-abroad opportunities in both forms, academic study and internships in the professional environment in question. In fact, the breadth and quality of the internships offered in full-fledged GSP programs, particularly in Business German, are a key attractor and a key indicator of their success. In addition, the privileged non-negotiable status of study abroad *cum* internship has a favorable washback effect on the at-home program inasmuch as it strongly points to certain curricular needs and their appropriately integrated pedagogies (von Reinhart, 2001).

The need to assure that students perform well in their study-abroad internships also translates into a compelling presence for “culture” that may well exceed that found in “regular” humanities programs, all the more so as GSP programs are keenly aware of and can readily point to the impact of different cultural contexts on the conduct of professional work (Hedderich, 1999; Grair, 2010). Such cross-cultural preparation is crucial in light of Kinginger’s (2008) finding that the value of a sojourn abroad, both for language learning and greater cross-cultural sensitivity, depends on the qualities of students’ experiences abroad as they interact with members of the other culture *and* their own personal stances in relation to those experiences. Both factors are explicitly attended to in GSP programs in the direct link to students’ chosen career paths. While no published studies exist, the admirable retention rates documented at URI as well as the graduates’ strong job placement record as indicated by internal studies provide highly suggestive corroborating evidence for the value of the nexus of work, study abroad, and the academic program itself (Rarick, 2009).

Performance-Oriented Pedagogies

Beyond the pedagogical practices that describe a communicative orientation, GSP pedagogies show several unique and highly desirable characteristics. The following stand out: (a) task-based teaching can become “real” with a palpable sense of immediacy and relevance; (b) collaborative project work can be taken directly from the world of the professions (e.g., engineering; business), thereby endowing in-class tasks with meaning and purpose (Setje-Eilers, 2007; Hager, 2009); (c) the prevalence of case studies, particularly in the business world, can be directly translated into extended, linked educational activities that advantageously blur the line between the inside world of the classroom and the outside world of work (Hoecherl-Alden, 2000; Ulrich, 2000); (d) additionally, all modalities can be readily connected, for example, purposeful reading, collaboratively discussing an issue in order to achieve a consensual course of action, and then presenting it formally, orally or in writing, in order to convey its key points and purposes (Weigert, 2004); (e) the task of learning rich disciplinary and technical vocabulary, a formidable hurdle for L2 learners, can be connected to a knowledge base that students generally already have (von Reinhart, 2001); (f) the need to acquire advanced ability levels, particularly in oral and written presentations and in negotiation environments, can be motivated and readily translated into demands and formats that show much similarity between classrooms and the world of work (Rarick, 2010); and (g) the purposive and audience-oriented nature of communication in the professions translates into the possibility of focusing on diverse verbal strategies of representation and patterns of meaning-making as they prevail in particular professional environments (Ryshina-Pankova, 2010).

In addition, the dearth of suitable instructional materials, the demand for up-to-date information on specific professional topics, the collaborative nature of the world of work, and the pervasive use of technology for information gathering and sharing and also for interacting in the world of the professions motivates a central position for technology in GSP education, turning it into medium and message, learning environment and professional environment, student-centered opportunity and work-oriented necessity (Hager, 2007).

Materials Development

As mentioned, lack of appropriate materials is a major challenge for GSP professionals and a constant focus of their attention. Once more, the disadvantageous situation is addressed primarily through collaboration and information sharing of materials that were developed through local initiative and on the basis of local experience of “what worked,”

for instance, in a particular course. In that sense, materials development in GSP is even less well theorized and supported by well-specified principles than it is in the FL overall.

Embracing an Assessment Orientation

Finally, an emphasis on assessment distinguishes GSP from regular German instruction. To date, opportunities for expanding horizons regarding classroom-based assessment in linked content and language learning remain to be seized in GSP as they do in FL studies in general (Byrnes, 2008). On the other hand, the non-negotiable demands of certification and licensing in the professions, the need for recognition of international standards, and the transferability of examination results have resulted in a noteworthy presence of diverse testing regimes in GSP. Most prominent are the intermediate-level, 2-day *Zertifikat Deutsch für den Beruf* (ZDfB; Certificate in German for Professional Purposes; http://en.wikipedia.org/wiki/Zertifikat_Deutsch_f%C3%BCr_den_Beruf), at the B2 level of the Common European Framework of Reference, and the even more challenging (above the C1 level) *Prüfung Wirtschaftsdeutsch* (PWD, Examination German for Business, <http://www.dihk-bildungs-gmbh.de/index.php?id=8>). They exert the kind of positive and negative curricular and pedagogical pressures, along with materials preferences and the need and opportunities for faculty development, that are commonly associated with national and international testing regimes.

With such characteristics, GSP presents considerable innovations for linking content and language learning, classrooms and the professional world, and learning in instructional settings and life-long learning. To date, it realizes the potential in an educational environment that, more often than not, is unsupportive of those efforts. Yet, as higher education considers its mission in relation to the nature of knowing and learning and as FL studies wrestles with assuring that FL programs enable students to acquire high levels of linguistic and intercultural competence for a globalized world, insights gained in GSP have the potential of showing useful directions for educationally sound practices.

My thanks go to Damon Rarick for personal communication about issues in GSP and to Mackenzie Barrow, my graduate research assistant, for help in compiling the bibliography.

Gesture Analysis in Second Language Acquisition

MARIANNE GULLBERG

Gestures—or bodily “actions that have the feature of manifest deliberate expressiveness” (Kendon, 2004, p. 15)—are an integral part of how we communicate. When we speak, we typically also gesture, and we deploy this rich expressive resource in sophisticated, systematic, and nontrivial ways (Kendon, 2004; McNeill, 2005). Contemporary gesture research shows that gestures are closely linked to language and speech in production, comprehension, and development. Gestures reflect and interact with cultural, linguistic, cognitive, and more general aspects of communication, showing systematic variation across a range of measures in each of these domains (see Kendon, 2004; McNeill, 2005). Although the predominant function of gestures is under debate (Kendon, 1994), scholars generally agree that gestures serve both addressee-directed (“interactive”) and speaker-directed (“internal”) functions in communication. Speakers thus produce gestures for addressees to convey meaning and structure; to clarify, disambiguate, and highlight messages; to regulate turn taking; and so forth (Holler & Beattie, 2003; Bavelas, Gerwing, Sutton, & Prevost, 2008; Streeck, 2009). Addressees also attend to and process gesture and speech together as an integrated message (Cassell, McNeill, & McCullough, 1999; Willems & Hagoort, 2007). Conversely, speakers produce gestures for themselves to help organize thoughts and facilitate their own expression (Kita, 2000).

Under this view, gestures are an integral part of communication in the same arena as speech and language, subject to crosslinguistic, sociolinguistic, and psycholinguistic variation. They therefore become a natural extension of second language (L2), foreign language (FL), and bilingualism studies, where they can be examined as a system to be acquired (the acquisition of gestures), as a medium of development (the effect of gestures on acquisition), and as a window on language development (gestures in acquisition). Gesture analysis can shed new light on familiar issues such as crosslinguistic influence, interlanguage, communication strategies, the role of interaction and collaborative processes, the role of multimodal input and output (processing) for acquisition and use, pragmatics, classroom practices, effects of study abroad, assessment, (mono- and bilingual) native-likeness, and so forth (see papers in Gullberg, 2006, 2010; McCafferty & Gullberg, 2008; McCafferty & Stam, 2008). This entry does not exemplify these research domains or discuss their theoretical underpinnings, but instead focuses on methodological aspects of gesture analysis.

Gesture Analysis in L2, FL, and Bilingualism Studies

What to Study and Measure

As in all research, the design and methodological details of studies involving gestures depend on research questions and theoretical frameworks. Decisions must be made concerning the choice between observational, naturalistic versus structured, elicited, and experimental designs; longitudinal versus cross-sectional formats; and case versus group studies. Multimodal behavior is complex and it is important to determine exactly what

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

DOI: 10.1002/9781405198431.wbeal0455

behavior (e.g., manual gestures, gaze direction, head movements, etc.) and what dimensions thereof are relevant (e.g., presence-absence, gesture frequency or rate, form, meaning, function, timing relative to speech, contextual use, order in sequence). That is, it is crucial to specify how gestures are identified and the relevant unit(s) of analysis. For example, gestures are variously defined as gesture “phrases” (all movement between two major resting positions: hands on lap—movement—hands on lap) or as gesture “strokes” (only the nucleus or apex of individual movements, disregarding preparatory movement or retractions of hands). Different gesture definitions obviously influence other analyses (e.g., of gesture rate), especially where gesture units are analyzed in relation to spoken units of analysis such as turns, utterances, clauses, or speech exactly aligned with the gesture. Methodological rigor and explicitness are crucial to replicability.

Note again that there is no simple way to determine the measures for a given research question that are most relevant to L2/FL/bilingual studies, but it depends on the theoretical framework. Studies have employed all dimensions listed above, but most frequently gesture rate (Pika, Nicoladis, & Marentette, 2006), gesture form and meaning (Choi & Lantolf, 2008), timing (Stam, 2006), function (Gullberg, 1998), and degree of co-expressivity with speech (Brown & Gullberg, 2008). Most studies involve gesture production, whereas studies of gesture comprehension are very rare.

Tasks and Participants

Like speech, gesture production is influenced by a range of contextual variables. Some tasks, settings, and topics are more conducive to gesture production than others. Naturalistic studies often do not use any “tasks” but record whatever activities interlocutors are engaged in. Elicitation tasks, in contrast, are often designed to promote spontaneous gesture production while keeping the content of speech and contextual variables constant to facilitate comparison across participants, and—importantly—minimizing speakers’ conscious awareness of their own gesture production. Most researchers hide the fact that gestures are of interest until after task completion. Elicitation tasks often involve narratives or story retellings, picture or video description tasks, or referential communication tasks on spatial or action-related topics. Some tasks also involve practical actions and object manipulation such as the use of dictionaries (Platt & Brooks, 2008). Since gestures are more frequent in dialogic face-to-face interaction (Bavelas et al., 2008), tasks and settings are often dyadic with confederate or naive interlocutors, although the private speech and gesture of individual speakers are also studied (McCafferty, 1998). Gestures are also more frequent when new information is conveyed for a communicative purpose (McNeill, 1992), making experimenters, who demonstrably already have relevant knowledge, unsuitable interlocutors. Finally, because gesture production co-varies with speech, tasks typically aim to elicit more than individual words or single utterances.

Gesture comprehension tasks could include everything from questionnaires, picture naming, and similarity judgment tasks to electrophysiological measures of the brain’s activity during comprehension.

Participants are typically L2/FL users at different levels of proficiency and fluency, bilinguals, and often also (monolingual and bilingual) native speakers as control groups. L2/FL users/bilinguals are often observed using both their languages (typically counterbalancing language order across participants in experimental studies). The same selection criteria apply as for other L2/bilingual studies regarding language background, age of exposure, proficiency, FL versus L2 learning, usage patterns, gender, socioeconomic background, and so forth. Note that since there is individual variation in the general propensity to gesture such that some participants hardly gesture at all, it may be necessary to record many more participants than are included in the final analysis to reach acceptable sample size. Unfortunately, the dropout rate is typically not reported.

Finally, in studies where comparisons are made of speech and gesture across groups, tasks, or time points, it is important to establish baselines. If L2/FL/bilingual speakers' gesture production is to be compared to that of monolingual/native speakers, it is crucial to establish the baseline variation in both groups. It is equally useful to determine variation within an individual, for instance to compare the same individual speaking the first language (L1) versus the L2, or the L2 in a simple versus a hard task, in fluent versus disfluent speech, before versus after some training intervention or study abroad, and so forth.

Data Collection

The study of gesture requires audio and video data, now typically in digital form. If video data are collected, participants' anonymity and privacy must be protected, and written consent to use video data, specifying contexts of use (seminars, scientific conferences, publications, etc.) should always be collected.

For production data collection, technical decisions to be made include the type of video (analog vs. digital), video format and sampling rate (number of video frames per second; PAL 25-NTSC 30), number of cameras (to capture an individual speaker vs. all speakers or the whole scene; details of face, etc.), recording angles (en face, from the side, from above, etc.), lighting and background, and use of separate audio-recording devices (recommended). In laboratory settings, motion capture technology allows body movements to be recorded in three dimensions (rather than two on video) using reflectors attached to the body tracked by infrared cameras. This technology provides high spatial (0.5°) and temporal (2 ms) resolution and allows for semi-automatic analysis. Further practical decisions concern the location (at home, in the classroom, in the lab), seating arrangements (face-to-face, side-by-side, with or without intervening furniture, physical distance between interlocutors, etc.), the visibility of cameras, and so forth.

For comprehension, technical decisions include the form and display medium of gesture data (static vs. dynamic images, display on TV/computer vs. big screen, small vs. life-sized projection, etc.), and the form of response data (interview data, questionnaires, immediate recall protocols, reaction times, etc.). In all cases, instructions should be explicit and replicable.

Transcription, Coding, Analysis

Gesture studies must transform visual data to easily analyzable formats via transcription and coding. A range of (free) software is available to annotate digital video (e.g., ELAN, www.lat-mpi.eu/tools/elan; Anvil, <http://www.anvil-software.de/>), the use of which facilitates the establishment of inter-rater reliability.

Determining how and what to transcribe is challenging since gesture studies lack a standardized transcription scheme (for two influential approaches see McNeill, 1992, 2005; Kendon, 2004). Most schemes target the temporal relationship between speech and gesture (when does the gesture move relative to speech?) and the kinetic properties of gestural movements (what moves where and how? i.e., articulator, place of articulation, movement trajectory, hand shape). Transcription usually proceeds frame by frame, although semi-automated systems are being developed.

Many further classification schemes (see Kendon, 2004, for an overview) invite scholars to code semantic or functional properties of gestures such as co-varying dimensions of iconicity, deixis, metaphoricity, and rhythm (McNeill, 2005) and communicative functions (e.g., self-regulation, attention-directing). Other coding categories include degrees of co-expressivity between speech and gesture, location in gesture space, and gesture size. Such coding schemes allow questions like the following to be addressed: Do L2 speakers

express missing lexis in gesture instead of in speech (co-expressivity)? Do English–Japanese bilinguals switch gesture size depending on language (location in space/gesture size)? Careful analyses of accompanying speech are also vital.

Analyses in L2/bilingual studies typically compare native monolingual to non-native bilingual speakers and often examine accuracy and appropriateness to determine degree of acquisition, proficiency, and native-likeness. This is more challenging for gesture than for speech. Only one gesture type, conventionalized gestures or “emblems,” with fixed form and meanings like the thumbs-up sign, can be coded for well-formedness. However, other, non-conventionalized gestures lack such standards. Comparisons must instead be based on more fluid measures such as similarities in preferential usage patterns.

Gesture rate, frequently analyzed in L2/bilingual studies (Pika et al., 2006), should be based on a computation of gesture frequency per some unit of speech rather than time (e.g., number of gestures/100 words) to account for the fact that gesture production covaries with amount of speech. L2 speakers may be disfluent and speak and gesture slowly. Comparisons to native speakers should reflect this difference.

Given the range of phenomena to study and the covariation of gesture with multiple aspects of communication, L2/bilingual gesture studies require creative designs and analyses. Both qualitative and quantitative approaches are needed to improve our understanding of speech–gesture interaction across cultural, linguistic, and learning contexts.

Gestures and speech form an audiovisual ensemble and gesture analysis opens new vistas on the full range of L2 speakers’ communicative and linguistic resources. As such, it is a crucial addition to the applied linguist’s analytical toolbox.

Gibbons, John

RICHARD POWELL

John Gibbons (1946–) is a major contributor to the fields of bilingualism and forensic linguistics. He is now semiretired in Australia, but his London roots still remain clearly detectable in his accent. While studying for his BA in Spanish and French at Exeter University, Gibbons spent a year in Spain teaching English. The experience sparked an interest in English-language teaching (ELT) as a way of pursuing his passion for travel. Graduating from Exeter in 1968, he took a Certificate in Education before spending two years teaching English and French at a Nairobi high school. He returned to the UK to teach English to immigrant children and in 1973 completed an MA at Lancaster University, focusing on linguistics for ELT. He subsequently took up a lectureship at the University of Hong Kong, initially in the Language Centre and then at the Education Faculty, where he trained English teachers and taught applied linguistics. The vibrant sociolinguistic environment of Hong Kong brought an enduring fascination with bilingualism. He wrote his doctoral thesis on Hong Kong bilingualism for Reading University under the supervision of Peter Trudgill and Frank Palmer, and gained his PhD in 1983. Some of this research was published as *Code-Mixing and Code Choice* (Gibbons, 1987).

Central to this work is the hypothesis that one language choice made by many Hong Kong speakers is a mixed code neither entirely Cantonese nor entirely English. While Cantonese tends to dominate this mixed code, it includes a great deal of English, especially nouns and verbs. Gibbons found the reason for inserting English vocabulary to be not so much that equivalent Cantonese words don't exist, or are unknown to particular speakers, but rather that speakers subconsciously find English terms more appropriate for certain topics and in certain social settings. An example frequently cited in the research is academic discussions in universities. The idea of mixed code as a positive language choice is now widely accepted in sociolinguistics.

In 1983 Gibbons took up a lectureship in Michael Halliday's Linguistics Department at the University of Sydney, running the MA program in applied linguistics. In 1987 he helped organize the AILA Congress in Sydney and coedited (with Halliday and Howard Nicholas) the subsequent collection *Learning, Keeping and Using Language* (1990). In Sydney he also expanded his interest in bilingualism and language maintenance, coauthoring a number of studies on the maintenance of Italian with Camilla Bettoni. His research, with Elizabeth Ramirez, into the maintenance of Spanish was summarized in *Maintaining a Minority Language* (2004).

An invitation to be an expert witness in a court case involving a second language speaker was the catalyst for Gibbons' other major academic interest: the relatively new field of forensic linguistics. Gibbons worked as an expert linguist on more than 30 cases for bodies such as the New South Wales Police, the Australian Federal Police, the Refugee Review Tribunal, and many prominent legal practices.

Forensic linguistics also has the wider meaning of the study of how law and language interface. With this sense in mind, Gibbons has authored a number of major texts on the nature of legal language and discourse, including *Forensic Linguistics* (2003), which was subsequently translated into Chinese and Japanese, and *Language and the Law* (1994), which was shortlisted for the 1995 BAAL book prize. He was chief editor (with H. Nagarajan,

V. Prakasam, and K. V. Thirumalesh) of *Language in the Law* (2004) and coeditor (with Maria Teresa Turell) of *Dimensions of Forensic Linguistics* (2008). With Dennis Kurzon he coedited a 100,000-word section on "Law and Language" for the *Encyclopedia of Language and Linguistics* (2005). One of Gibbons's aims has been to show how lawyers control witnesses by asking them questions that encourage them to fit their answers into a particular interpretation of the evidence while leaving them little room to present a rival picture. He has been active in encouraging police forces to issue clearer advice to suspects about their rights while under arrest. His experience of Spain and Latin America has enabled him to draw comparisons between the civil law systems of that part of the world and the adversarial legal systems found in most of the English-speaking world.

Gibbons served as President of the International Association of Forensic Linguists and as convener of the AILA Scientific Commission on Forensic Linguistics. He has published 60 academic papers, including four in the journal *Applied Linguistics*. He has also authored texts for English as a second language. His work, especially in the field of forensic linguistics, has attracted wide media attention, with newspaper reports, television appearances, and 20 radio interviews, including one for the BBC on voice identification of Osama bin Laden.

At the end of his career in Sydney, Gibbons returned to Hong Kong for three years from 2002 as a Professor at Hong Kong Baptist University, where he edited with Ng Sik Hung a special issue of *Journal of Language and Social Psychology* on "Thinking Bilingual and Acting Bilingual" (2004).

Now living in Melbourne, Gibbons is an honorary Adjunct Professor at the University of Western Sydney and holds dual British and Australian citizenship. He continues to receive invitations to teach courses around the world, most recently at the University of Malaya, Cardiff University, and Akita International University in Japan. He is on the editorial boards of the *International Journal of Speech, Language and the Law*, the *Journal of Multilingual and Multicultural Development*, and *Translation Watch Quarterly*.

Gimson, A. C.

JOHN WELLS

Professor Alfred Charles (A. C.) Gimson (1917–85) was the most influential British phonetician of the second half of the 20th century. He is known particularly as the author of the standard work *An Introduction to the Pronunciation of English* (1962).

Gimson grew up in London. He received his secondary education at Emanuel School in Wandsworth and then studied for a BA degree in French at University College London (UCL). It was there that he first came into contact with phonetics, by way of classes in French phonetics taught by Hélène Coustenoble in the Department of Phonetics headed by Professor Daniel Jones, the world authority on English pronunciation (and that of many other languages). He graduated with first-class honours in 1939, whereupon Jones recruited him as an assistant. Within a few weeks, however, World War II broke out. Gimson was called up into the British Army, where he put his language skills to good use, serving with distinction as a liaison officer first with the Free French and then with the Free Polish forces. By the end of the war in 1945 he had been promoted to the rank of major.

At that point Daniel Jones intervened to enable him to be discharged early from the army, to join the UCL Department of Phonetics as a lecturer. This was despite the fact that Gimson not only had no doctorate, but not even a master's degree. This shortage of qualifications would nowadays mean that such an appointment would be inconceivable. In the special circumstances of the immediate postwar situation, however, it was not unique.

Gimson never did acquire any higher degrees. Nevertheless, UCL did not hesitate to promote him in due course first to reader and then to professor, as the holder of the chair in phonetics previously occupied by Jones.

As well as general lecturing duties, Jones speedily enrolled Gimson to assist him in the task of running the International Phonetic Association (IPA) and helping to edit and proofread its journal, *Le Maître phonétique*. This journal was unique in that it was printed entirely in phonetic transcription. Many of the articles were in English, but the administrative matter was all in French, as were many of the short illustrative anecdotes published in its [parti dez elev] (*partie des élèves*, or Learners' Section). Gimson's ability in French phonetics, including the ability to write French in phonetic transcription, was clearly vital. In 1950, on Jones's recommendation, Gimson was elected secretary and treasurer of the association, a role which also involved the editorship of the journal. He remained a key figure in the IPA until his death 35 years later.

Over the first 20 years of Gimson's editorship of the journal, he gradually moved it more and more from being a members' newsletter with short scholarly notes to becoming a mainstream scholarly journal. But as a publication it was held back by the insistence on the exclusive use of phonetic transcription both for editorial matter and for articles by contributing phoneticians. This severely restricted the pool of potential contributors, while even those who could handle the task of composing in phonetic transcription may have felt inhibited when they attempted to express themselves on more technical or intricate matters. Furthermore, it restricted the size of the readership, since it made the journal inaccessible to all except the initiated, those who could read English and French (and sometimes other languages) in phonetic transcription. In those pre-electronic days it also made it very expensive to print, since the type could be set only by specially trained compositors. In 1970 Gimson made the important decision to switch the journal to ordinary

spelling, and to rename it *Journal of the International Phonetic Association* (JIPA). Since then JIPA has gone from strength to strength.

The IPA sponsors the International Phonetic Alphabet but does not specify a unique transcription system for particular languages. Thus there can be several competing IPA symbol sets applied to English. Not only in the IPA journal but also in the wider world, until the 1960s the phonetic transcription of English had mostly followed Jones's "quantitative" system, in which the long vowels were written with length marks and the short ones using the same symbols without the length marks. Thus *bead* was written as [bi:d] and *bid* as [bid], *caught* as [kɔ:t] and *cot* as [kɒt]. There was also a less widely used, "qualitative," notation system in which length marks were not used but the distinction between long vowels and the corresponding short ones was captured by the use of different letter-shapes: *bead* was written as [bid] and *bid* as [bɪd] (or alternatively [bɪd]), while *caught* was [kɒt] and *cot* was [kɒt]. Meanwhile in the United States other scholars had been experimenting with such notations as [biyd], [bid], [koht], [kot]. Over the period 1950–60 Gimson experimented with various other transcriptional solutions for "Southern British" English, trying them out in the journal. Finally he hit on the system which has now been adopted by almost all British phoneticians and has become the standard phonetic notation in British-published dictionaries and textbooks. This is a "qualitative-quantitative" system in which both length marks and distinct letter shapes are used to distinguish the pairs of vowels. We now write *bead* as [bi:d], *bid* as [bɪd], *caught* as [kɔ:t], and *cot* as [kɒt].

Gimson's other main transcriptional innovation for English was the replacement of Jones's [ou] (ou) in words such as *goat* by [əu] (əu), thus reflecting the 20th-century pronunciation change in which the first element of this diphthong became central and unrounded rather than back and rounded.

These transcriptional decisions were launched on a wider audience in *An Introduction to the Pronunciation of English* (Gimson, 1962). This quickly established itself as the authoritative reference book on Received Pronunciation (RP, the widely accepted standard way of pronouncing British English). It has undergone several substantial revisions since then: a second edition was published in 1970 and a third in 1980. After Gimson's death a fourth edition, revised by Susan Ramsaran, was published (Gimson, 1989). Following Dr Ramsaran's withdrawal from academic life, subsequent editions have been edited and extensively revised by Alan Cruttenden, under the revised title *Gimson's Pronunciation of English* (Cruttenden, 1994), with subsequent editions in 2001 and 2008. Gimson's book has thus been the standard work on the subject for half a century and is likely to retain this position for many years more.

Gimson also produced two textbooks aimed at the English as a foreign language (EFL) market. The first was *English Pronunciation Practice* (Arnold & Gimson, 1965/1976) and this was succeeded by *A Practical Course of English Pronunciation: A Perceptual Approach* (Gimson, 1975). As the title implies, the latter in particular places great stress on ear training as a necessary part of pronunciation learning. The influence of American structuralism can be seen in Gimson's extensive use of minimal pairs for exercises in both perception and production.

In 1971, on the retirement of Dennis Fry, Gimson became head of a newly amalgamated Department of Phonetics and Linguistics at UCL, combining Jones's Department of Phonetics with the Department of Linguistics founded by M. A. K. Halliday. (This amalgamation was reversed in 2007 when UCL reorganized it into two "research departments" of speech, hearing, and phonetic sciences on the one hand and linguistics on the other.) Prior to Gimson's appointment, there had been no undergraduates registered in the department: under Jones and then Fry, phonetics had been taught only to students from other departments, occasional students, and postgraduates. Under Gimson there came to be two undergraduate degrees provided by the department: the BA in Linguistics and the BSc in Speech

Sciences. Not only as head of department at UCL, but also as a council member of the College of Speech Therapists (now the Royal College of Speech and Language Therapists, or RCSLT), Gimson played a major role in making speech and language therapy (SLT) an all-graduate profession. Previously, the accrediting qualification had been a licentiate or diploma rather than a bachelor's degree. Nowadays, though, SLT training in Britain and Ireland is usually delivered in the form of a three- or four-year university first degree, accredited by the RCSLT. (In the United States, on the other hand, such training is delivered exclusively at the master's level—which is also possible in the United Kingdom.)

During the last 10 years of his life Gimson suffered from heart problems, which were treated with the then recently discovered beta-blocker drugs. He died from an unexpected heart attack while mowing his lawn using a manual lawn mower.

Although this biographical note reveals his full name, Gimson never used his first names: he always published as A. C. Gimson or A. C. G. Even his friends and colleagues did not know what his initials stood for. In the university and among phoneticians he was always known formally as (Professor) A. C. Gimson and informally simply as “Gim.” (In both the long and short forms of his surname the [g] was “hard,” i.e., a velar plosive.)

Gorter, Durk

ALEX M. J. RIEMERSMA

Durk Gorter (born 1952 in Friesland, the Netherlands) grew up bilingually in Frisian and Dutch from birth. He was educated in sociology at the University of Groningen, the University of Amsterdam, and the University of California Santa Barbara (USA). His PhD thesis was on language use and code switching of local civil servants and their clients in Friesland (Gorter, 1987a, 1993).

In 1978 Durk Gorter was the first scholar in the sociology of language appointed at the Fryske Akademy, the research institute on the language, history, culture, and society of Friesland (founded in 1938). As from 1994, he combined his work at the Fryske Akademy with a part-time professorship of Frisian sociolinguistics at the University of Amsterdam. His appointment, in 2008, as a research professor with the Ikerbasque foundation at the University of the Basque Country (in Donostia-San Sebastián, Spain) is a significant development in his academic career. He continues to be involved in joint research activities between the University of the Basque Country and the Fryske Akademy.

His main fields of research are multilingualism, comparative studies of European minority languages in education, and the linguistic landscape. He has participated in various European research projects, edited books and special issues of journals in his fields of specialization, and has been involved in the organization of international meetings such as the series of International Conferences on Minority Languages (ICML) that started in 1980 (Gorter, 2009).

He started his career as one of the researchers in the project “Taal yn Fryslân” (Language in Friesland; 1979–84); this is the most complete and highly valued survey on language use and language attitudes in Friesland. It comprises a thorough sociological study with over 1,000 respondents throughout the province of Friesland. The study focused on language competencies, language use in various domains (education, media, church life, and leisure time), as well as reading habits, language attitudes, ideology, identity, and language policy. The study included also the use of Dutch as the majority language and the non-Frisian dialects within Friesland (Gorter, Jelsma, Van der Plank, & De Vos, 1984; Gorter, 1987b). The survey was repeated a dozen years later as the project “Taal yn Fryslân op ‘e nij besjoen” (Language in Friesland revisited; 1993–6). The overall results showed that while the oral use of the Frisian language (94% of the population understand Frisian and 74% are able to speak Frisian) as well as the reading competence (65%) remained stable, the reported proficiency in Frisian writing increased from 11% in 1980 to 17% in 1994 (Gorter, 1994; Gorter & Jonkman, 1995). The survey project in Friesland was part of the European Language Surveys Network (1994–9), which comprised similar survey projects in the Basque Country, Ireland, Wales, Catalonia, and Galicia.

Long before that Durk Gorter had become active on the European level. He was one of the founding fathers, together with, among others, Dónall Ó Riagáin and Helen Ó Murchú, of the European Bureau for Lesser Used Languages (EBLUL). This European organization for the protection and promotion of regional or minority languages in the European Union was created after the adoption of the Arfé resolution by the European Parliament (in 1981). He served on the Board from 1982 to 1990.

In 1987 the Mercator network was set up, with the help of the European Commission, to store and collect documentation and information and to carry out research on minority or regional languages. It comprised three centers: Mercator Education in Ljouwert/Leeuwarden hosted by the Fryske Akademy, Mercator-Media in Aberystwyth (Wales), and Mercator-Legislation in Barcelona. The network centers closely cooperated to offer a broad range of information services. In his position as project leader of Mercator Education, Durk Gorter initiated several projects—among others, the Regional Dossier series which to date reflects over 40 minority languages of Europe (www.mercator-research.eu). Furthermore, important studies on teaching materials, teacher training, preschool provision, and trilingual education were carried out. Around the time of the start of Mercator Education, in April 1988, he was one of the organizers of a European conference on primary education of and in minority languages in the so-called EMU project. Over 100 delegates representing more than 40 minority language communities came together in Friesland for the first time during the European Union's existence to discuss issues surrounding primary education (Sikma & Gorter, 1990).

Through his work for Mercator Education and his research publications Durk Gorter contributed significantly to European comparative studies on language planning policies regarding regional and minority languages (Extra & Gorter, 2001, 2008; Cenoz & Gorter, 2005, 2008a; Gorter, 2008). He was also a member of the stakeholder group on languages for the preparation of the Lifelong Learning Program 2007–13 of the European Union and he did advisory work on language diversity for the Council of Europe.

From 1998 to 2005 Durk Gorter was also the President of the *Berie foar it Frysk*, the Frisian Language Advisory Board to the provincial government of Friesland. During his two terms as president he contributed greatly to the shaping of Frisian language policy in the field of public authorities, education, and the media, based on his great scholarly expertise. The Frisian Language Advisory Board has substantially influenced the renewed Covenant on the Frisian Language and Culture which was agreed between the central Dutch government and the provincial administration of Friesland in 2001 for a period of 10 years. The Board was also involved in guiding the process of implementation. The idea of co-responsibility of provincial and local municipalities for language planning was developed in a “menu system” based on a similar menu system in part III of the European Charter for Regional or Minority Languages of the Council of Europe.

In the Network of Excellence SUSDIV (Sustainable Development in a Diverse World) (2005–11) in the 6th European Framework Program, he became one of the task leaders. In this network he was able to develop the dimension of language diversity and multilingualism, amongst other things, through a focus on the newly developing field of linguistic landscape studies (Gorter, 2006; Cenoz & Gorter, 2008b; Bracalenti, Gorter, Santonico Ferrer, & Valente, 2009; Shohamy & Gorter, 2009; Gorter, Marten, & Van Mensel, 2011).

In his recent post at the University of the Basque Country Gorter has established the Donostia Research Group on Education And Multilingualism (DREAM, www.multilingualeducation.eu). His innovative research projects on multilingual education in the Basque Country (where Basque, Spanish, and English are used) compared to Friesland (where Frisian, Dutch, and English are taught), already show some interesting outcomes (Gorter & Cenoz, 2010; Cenoz & Gorter, 2011).

Durk Gorter's work has influenced the comparative study of European minority languages. He has been seminal for the development of linguistic landscape studies and currently he is involved in promising new work on multilingualism and education.

Graded Readers

RICHARD R. DAY

Introduction

Graded readers occupy an unusual space in foreign language (FL) teaching—unusual because many in the FL profession, particularly teachers, regard them as a valuable and indispensable resource while others, particularly FL researchers and theorists, view them with disdain. The strengths and weaknesses of graded readers (GRs) are discussed in this entry, with the aim of showing how helpful they can be not only in the teaching and learning of FL reading but in overall FL learning.

What Are Graded Readers?

When GRs made their first appearance in FL classrooms in the 1930s, they were reduced from the originals (e.g., classics, fairy tales, novels). The reduction (or simplification) involved using vocabulary and syntax appropriate for the grade (or level). However, as Hill notes (1997, p. 57), GRs originally written for FL learners appeared in the 1960s. As a result, terms such as “reduced” or “simplified” are not now generally used when discussing GRs. Rather, it might be more accurate to use the term “appropriate”—appropriate vocabulary, syntax, length, complexity, and genre for a particular grade.

The vocabulary used in GRs is determined primarily by frequency of occurrence. Unfortunately, each publisher uses its own frequency list so it is a bit difficult to say that the 200 most frequent headwords in a series from one publisher is the same as the 200 most frequent headwords in a series from another publisher.

In addition, GRs are sometimes based on analyses of commonly occurring words in related course materials. Authors also are allowed to use words not in its vocabulary list for a particular level if doing so helps the story work better. Words outside a publisher’s list may be illustrated (particularly at lower levels), paraphrased, or put in context. Finally, some publishers allow authors to use words from the list for the next level up. Words that are outside of a level’s list are given in a glossary at the end of a GR.

Another characteristic of GRs is appropriate syntax, which means beginning levels have easy syntax while higher levels use more complex structures. As with word-frequency lists, publishers have their own lists of grammatical structures and there is no uniformity among publishers about what grammatical structures are the easiest.

In addition to appropriate vocabulary and syntax, the length of GRs is controlled. The lower the grade, the shorter the GR. GRs written for beginners may be 10 to 15 pages with many illustrations to help convey meaning. GRs written for advanced learners may be 80 to 100 pages with few, if any, illustrations.

GRs are also controlled for their degree of complexity. For example, the plot of a GR novel written for beginners (e.g., a starter level or stage) would not be as involved as a plot of a GR novel written for advanced learners (a Level 6). In addition, in the starter GR novel, there would not be as many characters as in the Level 6 novel.

2 GRADED READERS

Day and Bamford (1998) see GRs as “language learner literature.” They write:

We see the term of *language learner literature* as analogous to the terms *Young Adult Literature* and *children’s literature*—established genres in their own right. It includes fiction and nonfiction, original writing, and texts adapted for language learners. But whatever form it takes, language learner literature presupposes the integrity that marks genuine writing: that it be not a lesser version of something else but a fully realized, complete-in-itself act of communication between author and audience. The basis for judging the success or failure of language learner literature is therefore identical to that of other writing: the response of its readers—the sense they make of the experiences they have. (p. 64)

Therefore, another important characteristic of GRs is that there is a wide variety of genres, from fiction to biography to stage plays to factual texts (e.g., Oxford University Press’s *Factfiles*). GRs are written for a range of ages and tastes (e.g., romance, mystery).

Most GRs are in English, although there are some in French, German, Italian, and Spanish (Hill, 2008, p. 184). GRs in other languages (e.g., Mandarin, Arabic, Japanese) are needed.

Uses of GRs in FL Teaching and Learning

The primary use of GRs in FL classrooms is to teach FL reading. Most FL-reading experts posit two main approaches to the teaching of FL reading: extensive reading and intensive reading.

The intensive-reading approach may be seen as having three categories: grammar translation; comprehension questions and language analysis; and comprehension work and strategies. When GRs are used in an intensive approach, their roles are to provide a source for language study, for pre- and post-reading activities, strategy training, and vocabulary activities. Some GR series have many such activities either at the end of each chapter or at the end of the books. In addition, the learners may or may not read a complete GR.

An extensive-reading (ER) approach uses GRs very differently. The goal is for students to learn to read the FL. In an ER program, reading GRs is the primary focus. When students finish a GR, they select another one that is easy, interesting, and enjoyable, and read. They may engage in activities based on the GRs (e.g., Bamford & Day, 2004).

GRs are the foundation of an ER approach. Without GRs, an ER program cannot get off the ground. In a typical ER program, students start with GRs that they can read easily and that they find interesting and enjoyable. These initial GRs are in what Day and Bamford (1998, p. 92) call the students’ “reading comfort zone.” As they read a number of GRs in their reading comfort zones, they gradually move to the next level. So GRs that were initially too difficult become appropriate as the students’ reading ability improves. Their reading comfort zones have expanded. Ideally, the GRs serve as a bridge to texts written for L1 readers.

When students read a great deal of easy books that they select and read for overall understanding, they learn to read (e.g., Iwahori, 2008), develop positive attitudes and increased motivation to read, learn the FL (e.g., Yamashita, 2004), and make gains in oral fluency, vocabulary, grammatical knowledge, and writing (see Day & Bamford, 1998).

A third use of GRs is to teach FL literature—a class reader approach (e.g., Greenwood, 1988). The focus is on the story itself and students examine the GR for its plot, theme, setting, and so on. GRs may also be used to teach extensive listening (e.g., Brown, Waring, & Donkaewbua, 2008) when a GR comes with an audio source. Lastly, GRs may be the basis for a complete FL curriculum (e.g., Macalister, 2008). Hill (1997, 2008) claims that GRs have everything needed for students to learn the FL.

Issues in the Use of GRs

GRs, according to advocates, are a rich and valuable resource that belongs in an FL curriculum. However, GRs have detractors. Perhaps the most widespread criticism of GRs is that the language is simplified or not authentic and learners who read GRs develop strategies that are not appropriate for reading unsimplified language (e.g., Honeyfield, 1977). There have been numerous rebuttals to this issue (e.g., Day, 2003). Among the points they make are:

- There are multiple definitions of “authentic materials,” from texts written for L1 readers with no modifications (Scarcella and Oxford 1992, p. 98) to “a[n authentic] text can be one which is written for native speakers . . . or it may be a text intended for a language learner group” (Swaffar, 1985, p. 17).
- Materials written for an L1 audience and used with no modifications are too difficult for beginning and intermediate FL learners.
- Authenticity is not found in the text but in the relationship between the text and the reader.

A related criticism is that the simplified language of GRs is insufficient for FL learning. There is a robust literature that convincingly demonstrates that FL learners who read GRs in an ER program learn to read and increase their vocabulary knowledge (e.g., Pigada & Schmitt, 2006). Further, Day and Bamford (1998) summarized investigations of ER programs demonstrating gains in oral fluency, writing, and grammatical knowledge.

The Future of GRs

GRs have a long, albeit controversial, history. Given the developments with e-books and various devices to allow us to read texts digitally, we might wonder if traditional, hard-copy GRs will be replaced by e-GRs (see Eldridge & Neufeld, 2009). Whatever form GRs may take in the future, it is most likely a safe assumption that they will continue to play a valuable role in FL teaching and learning.

Grammar Analysis Techniques

WILLIAM CRAWFORD

The term grammar, while covering a wide range of topics ranging from the rules that generate phrases and clauses in a given language to the rules of “acceptable” language prescribed in usage books and style manuals, is used in this entry to refer to the structural description of rules that govern the linguistic behavior of a group of speakers. The unit of analysis for grammatical description of this type involves phrases and clauses (as opposed to intraclausal descriptions, the domain of discourse). From an *applied linguistics* perspective grammatical analysis is most relevant in two general areas: grammatical description and theoretical approaches to the development of grammar (in both first and second language contexts). These two areas can be quite different from one another, as descriptive approaches to grammar are not always concerned with making theoretical claims on language representation (as in many approaches to formal linguistics) or developmental claims (as seen in research in the area of second language acquisition). Grammatical description is, however, an important first step in theoretical work on grammatical development/change in that something needs to be described before it is explained. For example, a grammatical description may note that there are differences in the order of prepositional phrases following head nouns so that *the student of French with long hair* is an attested form but *the student with long hair of French* is not. This descriptive fact of English can be further explored from a theoretical perspective outlining the different structural relationships between a head noun and its associated prepositional phrases, and proposing an abstract syntactic category that accounts for this difference. The focus in this entry is on the grammatical analysis of English. The broad category of grammatical analysis covers both descriptive and theoretical claims of grammatical development or representation. This entry outlines the various techniques that have been used to analyze grammar from a variety of perspectives with a specific focus on second language development.

Counting Features

One of the most common techniques in grammatical analysis involves the quantitative analysis of selected grammatical features in a given set of data. Hinkel (2002) counted a wide range of grammatical features including tense, aspect, passive voice, infinitives, participles, noun clauses, relative clauses, and adjective clauses in both native and non-native argumentative essays to determine the extent to which the number and type of clauses in native essays differed from those produced by non-native essays. In this method of feature counting, Hinkel calculated a percentage rate for each grammatical feature by dividing the number of a given feature by the total number of words in each essay. Once the individual ratio for each feature in each essay was calculated, she ran a nonparametric statistical comparison (Mann–Whitney *U* Test) to compare the non-native essays by language background and with the native essay group.

Another method for counting grammatical features is found in the *Longman Grammar of Spoken and Written English* (LGSWE, Biber, Johansson, Leech, Conrad, & Finegan, 1999). This comprehensive grammatical description of English describes grammatical features in over 40 million words from four different registers: face-to-face conversation, academic

writing, news writing, and fiction writing. Since one main purpose of the *LGSWE* was to describe the distribution of grammatical features by comparing the frequency of a given feature across the four registers (which were not equal), the method for counting features involved computing ratios of the raw number of a feature in a given register divided by the total number of words in that register and then multiplied by 1,000,000. This process, called normalization (see Biber, Conrad, & Reppen, 1998), provides frequency counts on a scale (per million words) which allows for comparison across corpora of different sizes. For example if a given feature occurred 100 times in a spoken corpus of 1 million words and the same feature occurred 75 times in a 2-million-word corpus, it would be appropriate to normalize these counts by dividing the number of occurrences into the total number of words and multiplying the resulting number by a factor of 10 (e.g., 100, 1,000, 1,000,000). Using this procedure, normalization of the two corpora per million words would show that the given feature occurs 100 times per million words in spoken language and 150 times per million words in newspaper language. Additionally, due to the large amount of data, quantitative analyses in corpus linguistics often use automatic grammatical tagging, a process by which grammatical features are counted by computer programs (Leech, Garside, & Bryant, 1994). Grammatical tagging allows the researcher to use computer software programs to identify different grammatical categories, including parts of speech and grammatical constructions such as phrase types, clause types, and semantic classes of verbs.

Obligatory Contexts and Target-Like Usage

Obligatory context refers to cases where the presence of a given grammatical form is required. For example, in a sentence such as *She go to the store*, the subject-verb agreement rules of English require that the verb have the third person -s inflectional morpheme in order for it to meet the grammatical rules of Standard English. In such instances, the form of the verb that includes this inflectional morpheme—*goes*—is obligatory. Studies using the criteria of use in obligatory contexts approach are concerned with the extent to which a learner is supplying an accurate form when it is required by the context. In this sense, acquisition of a form is determined by the extent to which a learner is using the correct form in an obligatory context. First used in L1 acquisition research to compare the presence or absence of morphemes in child language by reference to occasions where a morpheme would be present in adult language (Dulay & Burt, 1973), the concept of obligatory context is also used in second language acquisition research (see Meisel, Clahsen, & Pienemann, 1981). Obligatory context research in language acquisition is generally determined by dividing the number of correct uses in obligatory contexts by the number of obligatory contexts and then multiplying by 100 to arrive at a percentage of correct suppliance. For example, if a learner has provided 15 correct forms out of 20 obligatory contexts, the percentage would be 75%. Some (e.g., Cazden, 1972) have claimed that acquisition is determined when the learner has used the correct form in an obligatory context at a rate of 90%. However, there are problems with this approach. For example, in some cases it is not always clear what the obligatory context is. In English, phrasal verbs with non-pronominal objects may occur directly after the phrasal verb—*He picked up the book*—or between the verb and particle—*He picked the book up*. In this case, there are actually two obligatory contexts, so calculating suppliance in obligatory context would require identification of variable contexts. Another problem with obligatory context research is that while obligatory context suppliance can provide information on how accurately a given learner uses a grammatical structure in the context in which it is required, it does not take into account cases where a form is supplied in a nonobligatory context such as *I traveling*

to *Italy last summer*. A suppliance in obligatory context approach would not count the progressive form of the verb and would potentially miss cases where a form appears in contexts where it is not permitted.

Another approach to characterizing grammatical development uses the concept of target-like usage, which characterizes language by analyzing all of the cases where a given grammatical feature appears (i.e., both obligatory and nonobligatory contexts). Calculating target-like usage involves adding the number of correct uses in obligatory contexts and the number of uses in nonobligatory contexts, dividing this by the total number of obligatory contexts, and then multiplying by 100 to arrive at a percentage. For example, if a given feature was used correctly 15 times out of 20 obligatory contexts but also overused the form an additional 5 times, the target-like use rate would be 60%. Pica (1984) has shown how these two approaches can arrive at very different conclusions by reference to the same data. While both obligatory context and target-like usage include the concept of accuracy in their analytical procedures, the decision to use either of them depends on the extent to which the research is interested in characterizing accuracy by reference only to obligatory contexts, or whether it is also interested in the extent to which a form is used both accurately and inaccurately. It should be noted here that both of these approaches require reference to native-speaker norms, and some have argued (e.g., Bley-Vroman, 1983) that such a comparison does not take into account the learner language in its own right. Such a criticism can be more readily addressed in a target-like use approach, which is not wholly concerned with accurate use of a given grammatical form.

Form-Function Analyses

Form-function grammatical analyses are based on the theoretical assumption that meaning (i.e., function) is primary in language and that grammar, semantics, and pragmatics are mutually dependent on each other. The types of analyses that are used in this framework are employed for both descriptive and theoretical reasons. The *LGSWE* is perhaps the most comprehensive example of form-function description of English grammar using a corpus-linguistics methodology. The *LGSWE* analyzes large samples of language gathered from specific situations of use (i.e., registers) by (a) identifying the frequency of grammatical (or lexical) features from texts and (b) providing a functional explanation for the quantitative findings. For example, the *LGSWE* reports that progressive aspect is more common in face-to-face conversation than in academic and news writing. This finding is then given a functional explanation related to the situational variables associated with face-to-face conversation such as purpose of communication and shared physical context, which results in a greater use of progressive aspect relative to academic and news writing.

In another approach to form-function analysis, language is seen in terms of pairings or "mappings" of grammatical form to semantic or pragmatic function, and function to grammatical form. The most widely accepted form-function view of language is found in Halliday's (1994) systemic functional grammar (SFG). While the intricacies of SFG are too complicated to describe here, the theoretical claim of SFG is that grammatical form can be related to three basic functions (each with a set of subfunctions). The main aim of SFG is to provide an explanation for how spoken and written texts are constructed to reflect the set of functions that comprise the basis of language.

Form-function analysis is also used in studies of language development. In a classic form-function mapping study, Huebner (1983) showed that the article *the* (produced by the learner as *da*) followed a set of developmental stages that corresponded to the extent to which the speaker believed that the noun following the article was known to the hearer, referred to a specific referent, and was functioning as the topic of the sentence. Using a

case study to illustrate the acquisition of the definite article, Huebner showed that the acquisition of the grammatical form of the definite article preceded the gradual acquisition of the target-like functions associated with it.

Error Analysis

The analysis of errors in learner language has a long history in the field of second language acquisition and teaching. In the late 1950s, L2 learner performance was thought to be related to the differences in the language systems of the native language and the target language (i.e., interference). In the 1960s and 1970s, an interest in looking at actual language performance resulted in the technique of error analysis. In this methodological approach to L2 acquisition, it was believed that a systematic account of learner errors served as the basis for language acquisition and teaching. It was further believed that errors (as opposed to mistakes, see Corder, 1967) should be viewed as systematic in the sense that they were indicative of a given learner's linguistic development. Although error analysis helped to shape the concept of interlanguage, it was not tenable from a theoretical perspective. One methodological problem with error analysis was the difficulty in selecting the linguistic source of the error. For example, if a learner produces a sentence with an agreement error such as *What factor make this successful?*, it is not clear whether the error is due to the lack of third-person singular marking on the verb or due to the lack of plural on the noun. Furthermore, it has also been shown (particularly in developmental sequence research) that certain learner errors can be indicative of language development.

While error analysis is no longer a popular theoretical tool for tracking L2 development in the sense that all errors are not equal (see discussion of developmental sequences below), the investigation of learner errors is still a popular issue in the field of L2 writing. Error-tagging (as seen in the Cambridge and the Longman learner corpora) can be helpful in showing frequent error types related to language background and proficiency level or other situational factors. Additionally, the concept of error is also relevant in the debate over the efficacy of error correction in L2 writing (see Ferris, 2006).

Accuracy, Fluency, and Complexity

The concepts of accuracy, fluency, and complexity are well represented in language-development research. The definition of these three concepts is hardly agreed upon by researchers, and this issue is addressed in the often-cited book by Wolfe-Quintero, Inagaki, and Kim (1998) where the authors report on a wide range of studies looking at complexity, accuracy, and fluency and the statistical support for the different ways these terms have been measured.

Of the three concepts, grammatical complexity is the most contentious. Complexity frequently uses the t-unit as a unit of analysis. First used to characterize the development of the writing of high-school-aged students by Hunt (1965), the t-unit consists of an independent clause and all associated dependent clauses. Complexity has traditionally been measured by calculating the ratio of number of clauses divided by the number of t-units, and grammatical development using the t-unit is characterized by the extent to which the ratio increases across grade levels in L1 high school students (Cooper, 1976) as well as proficiency increases in L2 learners (Hirano, 1991). Extending the concept of complexity to include a wider range of grammatical features and constructions in addition to the t-unit has also been a more recent development in research on grammatical complexity. Rimmer (2006) has argued that complexity is not solely related to the t-unit. For example, one can consider (a) different types of clauses (finite versus nonfinite) or (b) phrasal complexity

such as length of noun phrases or adverbial complementation as a measure of grammatical complexity.

Accuracy is defined as the extent to which language production adheres to a given language norm (even though what actually counts as a norm is dependent on language variety) or to situational variables such as level of formality or mode of communication. Hirano (1991) calculated a ratio of error-free t-units as a measure of linguistic accuracy; however, there are problems in identifying (and agreeing upon) errors, as noted by Polio (1997). One major factor in accuracy measure is to consider the extent to which individual errors are counted or whether a more holistic approach is used to characterize accuracy. While individual error counts can be useful in identifying specific types of errors, it is often difficult to establish agreement of these error types among different raters. Holistic accuracy scores do not provide information on specific error types but can often result in more agreement among raters.

Fluency has been used to refer to general overall language ability as evidenced by the amount or relative ease of language production, generally guided by the assumption that fluency is a good indicator of language ability. Fluency is measured in a number of different ways in both speech and writing. It has been measured in speech by reference to rate, number, and type of dysfluencies and pauses (Tavakoli & Skehan, 2005). In writing, fluency has been defined as the extent to which a given text adheres to the expectations of the audience in a given situation (Reynolds, 2005), by number of characters produced in a given span of time or text (Levy & Randsell, 1995), or by t-unit length (Hunt, 1965).

In addition to the variety of ways in which complexity, accuracy, and fluency have been measured, each of these terms is also important in various theoretical approaches to language development. The concept of syntactic complexity has been used in research investigating the extent to which explicit instruction (or lack of it) results in syntactically more complex structures—an area of investigation known as instructed SLA (Doughty & Williams, 1998). The importance of accuracy in SLA is related to Swain's comprehensible output hypothesis (Swain, 1985), which maintains that understandable production by L2 learners is a necessary condition in second language acquisition. Fluency has been considered to be a measurable aspect of L2 growth in the form of automatized procedural skill (Chenowith & Hayes, 2001). From a methodological point of view, complexity, accuracy, and fluency are often used as dependent variables in studies of language development with independent variables being proficiency, instructional treatment, or grade level.

Developmental Sequences

Work on developmental sequences (Pienemann, 1998) has shown predictable stages of grammatical development with learners from typologically different language backgrounds. Developmental sequences have been shown to occur for target-language word order, question formation, and negative structures and are best suited for researchers interested in the development of these particular structures. For example, in the negative sentence *I don't like that*, a learner may go through five stages of production with the target sentence being the fifth and final stage (i.e., stage one where a negator is placed directly before the verb in a subjectless sentence (*No like that*); stage two where there is a subject and a negator with no auxiliary verb (*I no like that*); stage three where there is variation between the presence or absence of an auxiliary verb (*I no like that/I don't like that*); stage four where a negator occurs with modal verbs (*I can't do that*) but not with an auxiliary verb (*I no like that*); and stage five where there is target-like production of the grammatical structure (*I don't like that*). Analyzing grammar with respect to developmental sequences allows for certain structures (even those that are not target-like) to be categorized into different types (or stages) and analyzed in relation to the extent to which they relate to other attested

stages of a given grammatical construction. For example, a learner who makes a stage-three error can be considered to be further along in their acquisition of negative structures than a learner making a stage-two error. Thus, grammatical analysis from a developmental-sequence perspective shows that not all errors are equal from a developmental perspective; some errors are more indicative of linguistic development than others.

Grammar and Discourse

OLGA DONTCHEVA-NAVRATILOVA

Grammar and discourse are key notions in linguistic studies, and are associated with two aspects of linguistic analysis. The study of grammar describes the system of rules and principles underlying the form and meaning of words, phrases, clauses, and sentences. The study of discourse explores language structures used in actual communication and analyzes the meaning conveyed by text in context, taking into consideration the participants' motivations, intentions, and purposes. Thus grammar and discourse may be seen as imposing different constraints on the selection of language resources that speakers of a given language have at their disposal. When we use language, considerations of grammar determine the set of structures available for the expression of a certain meaning and govern the choice of grammatical against ungrammatical forms, while discourse considerations motivate the selection of those grammatical means which can express context-dependent meanings and intentions in the most appropriate way. This entry will outline the most important aspects of the interaction between grammar and discourse, focusing in particular on the use and function of grammatical structures in different contexts of use and on the way grammar contributes to the organization of discourse.

Discourse Studies of Grammar

In recent years the study of grammar has gradually moved from a sentence-based to a discourse-based perspective. Discourse-based studies of grammar arose as a response to a growing awareness among linguists that the structural analysis of words, phrases, and sentences considered in isolation from communicative contexts is not enough to explain how grammatical structures are used in actual communication. The complex relationship between grammar and discourse is explored from different perspectives, reflecting the fact that the term "discourse" has different meanings to different researchers working in the heterogeneous field of discourse analysis. Despite the variation that exists, definitions of discourse and related approaches to discourse analysis may be seen as falling into three main categories: (a) language in use, (b) a stretch of language beyond the sentence, and (c) a culturally, institutionally, and ideologically determined social practice (Schiffrin, Tannen, & Hamilton, 2001, p. 1). Obviously, grammar is relevant to all these strands in discourse analysis. Nevertheless, most studies of grammar and discourse are associated with the first two approaches, since, as Biber, Connor, and Upton (2007, p. 1) observe, the third approach to discourse is rather socioculturally oriented and does not focus on purely grammatical phenomena.

Grammar can also be understood in a more restricted or in a broader sense. While commonly used to denote the morphology and syntax components of language, within some approaches to the study of language, such as generative grammar, the scope of grammar is extended to include pronunciation and meaning or to indicate a general theory of language (Jackendoff, 2002). Fundamentally, when approaching grammar from a discourse perspective, the study of language structure cannot be categorically delimited from semantic and lexical considerations. This is why many discourse studies influenced

by Halliday's (1985) functional-systemic theory use the term "lexicogrammar" to account for the interdependence of grammar and lexis in the process of encoding and decoding language meanings. In spoken discourse, some grammatical structures may in addition acquire phonological characteristics, for instance the phonological reduction of *going to* to *gonna* for the expression of intention or future meaning.

Discourse studies of grammar are typically empirical and frequently corpus-based. While dealing with the study of linguistic forms in actual communication, they use frequency analysis to determine the regularities of distribution of grammatical structures in discourse, and detailed analysis for the interpretation of the pragmatic (or communicative) value of established patterns of use. For example, recent studies have looked into the functions of the *get*-passive in spoken discourse (Carter & McCarthy, 1999), the use of non-extraposition in speech and writing (Kaltenböck, 2004), and the functions of the discourse marker *instead* in spoken and written discourse (Fraser, 2007). Most investigations are carried out on a selected discourse sample representing a particular language variety, and their findings cannot always be generalized as valid for any kind of context. This is because the functional specialization of some grammatical structures may be dialect-, register-, or genre-specific, reflecting differences in the circumstances of context, production, and processing typical of the respective language variety. However, the study of context-specific grammatical patterns is highly important because, when conventionalized in a particular context, these function as indicators of that context and may be exploited by users to create context-dependent associations (e.g., *I'm gonna* and *I gotta* are associated with informal spoken discourse). A growing number of discourse studies of grammar share a pedagogical perspective, aligning with Hughes and McCarthy's (1998, p. 280) view that, by exploring structural choices and issues of appropriateness in relation to language learning, the discourse-based approach promotes an awareness of interpersonal features of grammar and provides insights into areas of grammar previously lacking satisfactory explanation.

Functions of Grammar in Discourse

It is now commonplace to recognize that grammatical structures can perform various functions in discourse. There is, however, considerable difference between the way in which formalism, as illustrated by the generative-grammar tradition, and functionalism, represented by approaches building upon the traditions of the Prague School of Linguistics (Dušková, 2003) and systemic-functional theory, understand the notion of function. Formalist approaches advocate the primacy of the study of syntactic functions of grammatical forms at phrase, clause, and sentence level. Within a usage-based view of grammar, the focus is on the frequency of distribution of grammatical elements and their potential to acquire their own pragmatic and semantic characteristics, which have an impact on language variation and change (Bybee, 2010). The functional approach draws on Jakobson's (1960/1990) and Halliday's (1985) categorizations of language functions, which relate grammatical forms to the purposes participants want to achieve in communication, or, as Biber, Johansson, Leech, Conrad, and Finegan (1999, p. 41) observe, functions can be assimilated to tasks performed by linguistic features in discourse. Despite some variation in the categorizations of language functions, generally they can be subsumed under three basic macrofunctions: ideational, interpersonal, and textual.

The basic assumption of the functional approach is that these macrofunctions constitute the basis of the grammatical structure of a language, for grammar provides the means for the expression of participants' purposes in meaningful interaction. The ideational function, often regarded as the primary function of language, is performed by linguistic structures which identify referents in the context and convey propositional information about these

referents. Typical grammatical structures expressing ideational meanings include declarative clauses, presenting referents and propositions about them, and relative clauses and appositives specifying referents' identity. When conveying the interpersonal function, linguistic structures determine some aspect of the relationship between the participants taking part in the interaction and their attitude toward what is being communicated. For example, interrogative and imperative clauses regulate the interaction between the participants, while modality markers and stance adverbials indicate subjective attitudes, feelings, and emotions. Finally, grammatical structures performing textual tasks contribute to the build-up of coherent discourse by organizing the information structure or creating cohesion relations in text.

Variation in the Form and Functions of Grammatical Patterns in Discourse

In most languages grammatical structures may have several alternatives which express nearly equivalent meanings. However, these cannot be regarded as optional variants, because structural choices are influenced by various discourse factors. This kind of variation in English can be illustrated by numerous constructions. For instance, Biber et al. (1999) point out that pronoun realization in relative clauses is dependent on several factors, such as the type of relative clause, the animacy of the referent, and the context of use. While the relativizers *who* and *which* occur both in restrictive and non-restrictive clauses in more formal contexts, *who* is used exclusively with human head nouns and *which* typically does not combine with animate heads (1a). *That* combines with both human and nonhuman heads in restrictive clauses and triggers colloquial associations (1b). The omission of the relative pronoun is possible whenever the gap is not in subject position; it is favored in restrictive relative clauses with a pronominal subject because the subject form of the pronoun clearly indicates the beginning of a new clause (1c).

- (1a) The account which we develop of turn organization should be adequate to the analysis of conversation.
- (1b) I used to have more friends that would come for a drink on a Saturday night.
- (1c) I have lost the book I bought last week.

Choices of word order in adverbial positioning reflect variation in the functional specialization of adverbs. Thus in the case of *actually*, an adverbial associated primarily with spoken discourse, the initial position (2a) indicates a secondary linking function related to contradicting the expectations raised in the previous discourse (Oh, 2000; Taglicht, 2001) in addition to its function related to the expression of stance (2b).

- (2a) Actually, I find it difficult to explain this situation.
- (2b) I find it actually difficult to explain this situation.

The retention or omission of the complementizer *that* is dependent on the lexical verb, the subject of the main clause and the context of use. *That* is retained in academic prose especially when the main clause uses the passive voice (3a). The omission of the complementizer typically correlates with an informal conversational context, discourse and mental verbs (e.g. *think*, *guess*, *believe*, *say*), and pronominal subjects (3b).

- (3a) We were told that the situation was difficult.
- (3b) I think I'm ready *vs.* I'm ready, I think.

The case of the omission of the *that*-complementizer after the verb *think*, as in *I'm ready, I think*, is of particular interest, because it shows that established discourse patterns may over time turn into new grammatical conventions. This is related to the phenomenon of grammaticalization, which is defined as the process whereby "lexical items or phrases come through use in certain highly constrained local contexts to be reanalyzed as having syntactic and morphological functions" (Hopper & Traugott, 2003, p. 100). As several recent studies have shown, the clause *I think* with omission of the *that*-complementizer has been grammaticalized as a stance marker expressing modal certainty (Thompson, 2002; Ariel, 2009). As a result, similarly to adverbials, *I think* is not restricted to one position in the sentence. Other examples of grammaticalization in English are the *going to* structure for the expression of future time and *now* as a topic-changer (Aijmer, 2002).

Grammar and the Organization of Discourse

A prominent aspect of the relationship between grammar and discourse concerns the role of grammar in structuring discourse. When the participants in an interaction create and interpret a discourse, they perceive it as a meaningful whole fulfilling a particular purpose in a context of use. This involves the use of grammatical structures for organizing the information flow and the use of cohesion markers to guide the listener or reader toward the intended discourse interpretation.

Information Processing and Grammar

While approaching discourse processing from a psychological perspective, the study of information structure is concerned with the degree of familiarity and unexpectedness of the information conveyed to participants in communication and with the way in which given and new information is structured at sentence and text level. At sentence level, information structure is related to the syntactic structure of the sentence. In most languages, a normal or unmarked word order is associated with the occurrence of less prominent thematic elements at the beginning of the sentence and the positioning of more prominent elements at the end (e.g., Halliday, 1985; Firbas, 1992; Hajičová, Partee, & Sgall, 1998). In languages with flexible word order, such as Finnish or Czech, the perspectivization of the sentence toward the rheme or focus, in other words the most prominent sentence element, is considered to be the main principle regulating word-order choice. However, languages with a more or less fixed grammatical word order, such as English or French, have developed special structures to indicate the communicative value of sentence elements. While in spoken discourse prominence may be indicated by intonation, in written language it is the ordering of the components of the syntactic structure that indicates their relative importance.

When presenting and organizing information within a text, the speaker or writer can use a variety of grammatical structures to present some items as thematic and established in the text, and others as rhematic and more prominent. For instance in English, the grammatical constructions available for structuring information include the passive-voice construction, cleft structures, inversion, extraposition, and left- and right-dislocations. As Huddleston and Pullum (2002, p. 1365) observe, these structures differ syntactically from the more basic or canonical constructions in the language in the way in which information content is presented. By changing the normal word order of the sentence by breaking it into two parts, cleft structures help the speaker or writer to identify clearly the most prominent element in the sentence (4a), while left-dislocations are used primarily to reintroduce and highlight given information (4b).

- (4a) It is the brown jumper that I am looking for.
- (4b) Roger, I haven't seen him for ages.

The passive voice can be used to leave the agent unexpressed because it is clear from the context (5a), unknown, or unimportant from the point of view of the discourse. When a subject noun phrase is very long, the passive (5b) allows it to be moved to sentence-final position to abide by the end-weight principle (Quirk, Greenbaum, Leech, & Svartvik, 1985).

- (5a) The parliament was dissolved.
- (5b) The project was carried out by scientists who have developed a new method for data analysis.

In academic discourse the passive is associated with leaving generic subjects unexpressed (6a), thus establishing the action as the focus of attention (Biber et al., 1999, p. 938). The use of the passive with the impersonal *it*-construction in self-sourced reports helps reduce author visibility (6b) and may be interpreted as a hedging device (Charles, 2006, p. 509).

- (6a) Information processing has been studied from different perspectives.
- (6b) It has already been pointed out that there is a tendency to overuse passives in academic writing.

Coherence, Cohesion, and Grammar

In actual communication, words, clauses, and sentences are put together to form a well-connected spoken or written discourse which makes sense in a particular situational context. The unity of a discourse is accounted for in terms of coherence, defined as the unity of meaning and communicative purpose perceived in discourse in a context of use (Cook, 1989), and cohesion, based on semantic and formal relations between the elements of a discourse which are expressed in that the interpretation of the meaning of one element in the discourse is dependent on the meaning of another (Renkema, 2004). Despite variation in views on the interdependence of cohesion and coherence, most researchers agree that discourse coherence is enhanced by markers of cohesive relations holding between lexical items and grammatical structures which overtly connect clauses and sentences (e.g., Hoey, 2001).

Perhaps the most comprehensive account of grammatical cohesive devices is provided by Halliday and Hasan's (1976) book *Cohesion in English*, in which the authors identify four classes of grammatical cohesive ties: conjunctives, reference, substitution, and ellipsis. Substitution, the replacement of one language item by another, and ellipsis, the omission of recoverable elements normally required by grammatical structure, are very similar procedures, and some linguists refer to ellipsis as substitution by zero. The omission or substitution of nominal, verbal, or clausal elements is typical of spoken discourse where it creates cohesive links between adjacent turns in a conversation (7a, 7b).

- (7a) Is she coming? I think so. (verbal substitution)
- (7b) Have you heard his story? Yes, I have. (clausal ellipsis)

While substitution and ellipsis operate on a local level which typically connects adjacent sentences and clauses, reference expressions may interact with lexical cohesion to form extensive cohesive chains which may connect larger segments of discourse. Reference expressions are those language items whose semantic interpretation is achieved by reference to something else in the discourse or in the situational context. Prototypical

reference devices are personal and demonstrative pronouns which may be anaphoric (i.e., referring backward to preceding discourse) or cataphoric (i.e., referring forward to upcoming discourse). The choice and use of reference devices depends on the semantic and grammatical distinctions in the pronominal system of a language (e.g., number, gender) and on the established patterns of use (Wales, 1996). While anaphoric reference is very frequent (8a), cataphoric reference is less common, and, as Halliday and Hasan (1976, p. 68) claim, “*this*, together with the parallel use of *here*, is the only significant instance of cataphoric cohesion in English” (8b).

(8a) Robert arrived late. He was extremely tired.

(8b) What I want to say is this: I will never give my support to your project.

The cohesive effect of referring expressions results from their potential to establish their referents as thematic across larger parts of the text, thus organizing discourse by reflecting what Tanskanen (2006, p. 109) calls topical segments.

Conjunctives may create relations of addition, contrast, cause, and temporal sequence holding at local and global level. For instance, *actually*, *however*, and *still* create relations across longer stretches of discourse, while *but*, *now*, and *then* establish local coherence relations (Lenk, 1998). Cohesive relations established by linking adverbials may be external, that is referring to relations between experiences of the participants in the communication (9a), or internal, organizing the flow of the discourse itself (9b).

(9a) (First he finished the book.) Then he fell asleep.

(9b) (First he was exhausted.) Then he was unable to decide what to do.

Grammatical cohesion is not always restricted to the relations described above. Some researchers (e.g., Quirk et al., 1985) extend the scope of grammatical cohesion by including such phenomena as voice, tense, and aspect.

Conclusion

Discourse-based studies of grammar seek to explore how patterns of grammar are used in the context of actual communication. While studying the distribution of forms across different spoken and written registers and genres, the discourse-based approach enables us to see that functional and structural variations in language are systematic and principled. It also shows how grammar is used to organize a stretch of language into a coherent and cohesive discourse. In short, discourse-based studies of grammar reflect an awareness of the fact that without an adequate understanding of discourse-affected choices it is impossible to understand or learn a language properly.

Grammar and Doctor–Patient Communication

DANIEL HUNT AND KEVIN HARVEY

Many forms of health communication are, principally, realized through spoken interaction. Although written language forms an important part of many health communication routines, studies into health language have predominantly focused on verbal interaction, in particular the general practitioner–patient consultation (e.g., Mishler, 1984; ten Have, 1989; Heritage & Maynard, 2006). The doctor–patient dyad has come to typify exchanges between health professionals and patients, with research identifying a number of grammatical and stylistic properties that inhere in this type of encounter. Identifying and describing these grammatical features in context has enabled researchers to provide both theoretical and practical insights into the dynamics of the medical encounter, insights that have contributed significantly to the study of health practitioners and patients (Sarangi, 2004, p. 2) and have deepened our understanding of contemporary healthcare.

This entry examines a number of the grammatical features that occur in and characterize the discourse of the medical interview. To offer some insight into the variable contextual use of spoken grammar, both syntactic characteristics that maintain professional authority and those that actively involve the patient in interview process are considered. In order to present a more comprehensive and varied survey, the focus also extends beyond purely physician personnel and their interactive routines. The aim in so doing is to represent other healthcare workers who have featured less frequently in health language studies, as well as drawing attention to the communicative routines of personnel who, besides frontline doctors, play an essential, if overlooked, role in the healthcare system.

Grammar and Spoken (Health) Communication

As Carter (2004, p. 25) observes, grammars of English have been based upon written language, taking the written mode of expression as “a benchmark for what is proper and standard in the language.” Consequently, spoken language, and the grammar of spoken language, has been comparatively under-studied. Given that spoken language represents communication at “full stretch” (Carter, 2004, p. 26), it is noteworthy that the grammar of spoken language has been, until recently, relatively neglected. It is not surprising, therefore, that a number of grammatical features common in spoken language do not conform to accounts given of them in traditional descriptive grammars (McCarthy & Carter, 1995). One might even go as far as saying that, for 20th-century linguistics, many of the linguistic features typical of spoken communication have been dismissed as “peripheral” to grammatical enquiry (Carter, 2004, p. 26).

Despite the research emphasis on written communication, the analysis of grammatical features in spoken health language affords an effective means of interrogating patterns in healthcare communication, enabling us to identify grammatical commonalities that characterize this particular mode of professional interaction. Spoken health communication routines possess a number of recurring lexicogrammatical signatures, thumbprints that characterize clinical encounters and distinguish them from other forms of spoken inter-

action. Accounting for the full range of these linguistic signatures is beyond the scope of this entry and so, accordingly, the focus will be restricted to a selection of grammatical features that best demonstrate both the exchange of information and power play that have been routinely identified in a range of spoken healthcare encounters. As will soon become apparent, these characteristic grammatical features do not simply function as mere structural constituents of talk. Rather, they play a dynamic and vital part in determining the outcome of clinical interviews, reflecting the goals of the institutions in which such exchanges take place, as well as reflecting the shifting roles and identities negotiated by the participants throughout interaction as it unfolds moment by moment.

Grammar and Control

The grammar of spoken interaction plays a pivotal role in constructing and negotiating our own social identities and those of our interlocutors. Within the context of a clinical interaction, speakers have institutionally defined roles—patient, nurse, doctor, physiotherapist, psychiatrist, and so on—that align with unequal distribution of power in social interactions. Traditionally this has been born out in the contextual authority of doctors to shape the medical encounter, investigating the complaint of the patient, providing a diagnosis and prescription on a subsequent course of action. However, the authority of the health practitioner in the medical encounter is neither inherent nor absolute and may be questioned or undermined by themselves or the patient. Thus professional identity and its attendant authority and interactional control is something that both doctors and patients must continually negotiate through discourse, of which grammar plays a fundamental role.

Ribeiro's (1996) illuminating study of psychiatric discharge interviews provides a powerful example of the uses of spoken grammar to control a clinical encounter. Ribeiro analyzes extracts from the interview of a 61-year-old Brazilian woman who has been admitted for 20 days following an acute psychotic episode. Both extracts are largely structured by the elicitations of the interviewer, a 25-year-old psychiatrist, who asks the patient a number of closed questions, beginning with:

(1) Doctor: You were born on what date? . . .

(2) Patient: On January 11th.

(Adapted from Ribeiro, 1996, p. 185. Ellipses represent pauses of half a second)

Unlike the normal grammatical structure of a *wh*- question such as "What date were you born on?" the doctor brings the grammatical subject, *you*, to the front of the clause, rather than the adjunct. Restructuring the question in this way immediately establishes the focus of the interview upon the patient by grammatically emphasizing the patient herself in the question's syntactic structure. From the start of the interaction, the doctor indicates that the patient is the subject of the interview, constructing her as a patient who is being examined, rather than, for example, attempting to establish a more symmetrical relationship. A number of the doctor's subsequent questions also have a marked grammatical form:

(5) You have a son, don't you?

(11) You also have a granddaughter, don't you?

(23) You live with your two sisters, don't you?

(Adapted from Ribeiro, 1996, pp. 185–6)

In all three of these examples, the doctor deviates from the typical syntax of an interrogative clause, again fronting the subject *you* to retain emphasis on the patient. Yes-or-no

questions such as those used by the doctor establish an “adjacency pair” (Schegloff & Sacks, 1973; McCarthy, 1998), in which the patient’s next utterance is conditioned by what the doctor has said; that is, in order to maintain the flow of the conversation, she is obliged to immediately answer the doctor’s question. The questions are also formulated as negative tags, added on to the end of freestanding, affirmative clauses. Carter and McCarthy aver that as well as allowing a repetition—and hence further emphasis—of *you*, tag questions are “highly interactive in that they may constrain the range of possible or desired responses from the addressee” (2006, p. 725), with negative tag questions in particular conveying an expectation that they will be affirmed. Thus not only does the adjacency pair established by the questions mean the patient’s utterances come in the form of answers, the content of her answers are strongly constrained by the marked grammatical form of the doctor’s questions. That is, the negative tag questions limit the patient’s ability to disagree with the doctor or to provide more expansive answers to her questions without also risking a challenge to the discursive structures established by the doctor. Utilizing grammatical structures particular to spoken grammar, the healthcare professional is able to determine the development of the conversation along strict lines that allow her to maintain interactional control and demonstrate her professional authority over the patient. Accordingly, the patient frequently gives the contextually appropriate, minimally informative responses.

However, when asked about her granddaughter, the patient changes noticeably. She becomes more animated, making increased eye contact and smiling more frequently. There are similar changes in the grammar of her responses:

(12) Patient: She’s my life

...

really. I am crazy (about her).

I like (her) ve-

...

(16) Patient: I don’t take care of her because my daughter-in-law takes very good care, y’know. . . .

I just see her, and all that. (I don’t)

(17) Doctor: Do you always keep in touch with them?

(18) Patient: Oh, yes, always. . . .

well as much as possible I do, y’know doctor . . .

(Adapted from Ribeiro, 1996, pp. 185–6. Words in round brackets indicate uncertain transcription; underlining indicates prosodic stress)

As Ribeiro notes (1996, p. 187), the patient now begins to use more complicated syntax, including previously absent adverbs and adverbial clauses to elaborate upon her answers. She says she “always” keeps in touch, before modifying this with the adverbial clause “well as much as possible.” She also makes repeated use of the discourse marker “y’know.” *You know* occurs frequently in spoken language and particularly in casual conversation and is used to express a subtle range of meanings. It is generally regarded as a means of foregrounding the interpersonal nature of a conversation, highlighting a common ground of shared knowledge with an addressee and expressing intimacy and rapport with them (Aijmer, 1984, 2002; Fox Tree & Schrock, 2002). The patient’s use of *you know* here foreshadows similar expressions when she is later discussing the pain of childbirth:

(2) Patient: . . . I thought childbirth was terrible. the pain, . . . y’know,

...

(6) Because the pain is terrible, isn’t it, doctor.

(Ribeiro, 1996, p. 179).

In each case the patient uses interpersonal discourse markers when discussing personal feelings to attempt to create a sense of mutual understanding and to encourage the doctor to align with her experiences, underlined by her direct address to the psychiatrist herself in “y’know doctor.” In these isolated exchanges, the patient uses grammatical discourse markers typical of informal speech in conjunction with prosodic signals and paralinguistic body language to demonstrate a capacity for the casual interaction that characterizes life outside of psychiatric institutions. This shift into the grammatical structures of casual conversation signifies an attempt to establish a more personal genre of interaction than is offered by the clinical interview hitherto, and one in which the patient can also occupy an alternative identity to that of psychiatric patient. These attempts to establish a noninstitutional genre of conversation, in which professional medical authority would be less relevant, are swiftly curtailed by the doctor who recommences her closed questions and refocuses the interview squarely on the patient by using her title and name: “Where do you live, Mrs Cardozo?” (Ribeiro, 1996, p. 186).

Despite being an exit interview in which the patient must demonstrate her capacity to rejoin society beyond the psychiatric institution, the patient is prevented from linguistically conveying a personal social identity. Rather, the particular grammatical constructions used by the interviewing healthcare professional prevent the interview from proceeding on a casual footing, maintaining her professional identity and Mrs Cardozo’s conversational deference. Where the patient seeks to reframe the interview and identify herself as a grandmother, making use of the appropriate grammatical structures of involved, casual conversation, her efforts are prohibited by the doctor’s ensuing questions (see Fairclough, 1992, pp. 137–49). As Ribeiro rightly asserts, the doctor’s discursive strategy, in which her grammatical choices play a fundamental role, “seems rather at odds with the rehabilitating purpose of a psychiatric treatment” (1996, p. 190). Thus, not only do the doctor’s grammatical choices largely control the course of the interview, they also control the social identity the patient is able to inhabit, something which will have a significant impact on whether or not she is released from institutional care. Such research serves as a reminder that the lexicogrammatical choices that act to maintain clinicians’ professional identity need not be in the interest of patients themselves.

Grammar and Patient Involvement

The diversity of contemporary healthcare practice means that medical information is now dispensed by a range of professionals through a variety of different media, including e-mail, real-time Web messaging, and telephone conversations, each of which engender specific communicative parameters and constraints. Foremost among these is the distance between the healthcare professional and the individual seeking medical advice, meaning that symptoms must be discussed and their severity assessed without the potential for visual or physical assessment of the patient. One contemporary example of such technology-mediated clinical discourse is the British NHS Direct service, a 24-hour telephone helpline established in 1998 to offer expert medical advice and information to callers in the United Kingdom. As part of a wider project involving the compilation and interrogation of the million-word Nottingham Health Communication Corpus, researchers made several recorded calls to the NHS Direct service with a view to investigating the details of this novel professional–patient interaction. Subsequent research into the data (Adolphs, Brown, Carter, Crawford, & Opinder, 2004; Adolphs, Atkins, & Harvey, 2007) has revealed a number of discursive strategies deployed by clinicians to compensate for the lack of physical proximity and provide a comprehensive appraisal of the patient. Most notably, the healthcare professionals on the NHS Direct service make a number of grammatical and lexical choices to maximally involve the patient-caller in the encounter through the

stages of symptom assessment, advice giving, and conversation closing. Most obviously, this can be seen by the frequent use of back channels. These one-word response tokens such as “yeah,” “mmm,” and “right,” are common in conversation but occur significantly often in the health advisor’s speech. Typically considered a means of demonstrating active listening and encouraging further talk (McCarthy, 1998, p. 58), within the clinical context they encourage patients to continue speaking and provide as much information as possible. Further, the minimal syntax of back channels—“right” as opposed to “that is right”—ensures that they do not constitute interruptions that would cut the patient-caller short. Larger grammatical structures are also evident. For example, in one call recorded by researchers the female healthcare advisor makes extensive use of coordinating conjunctions while attempting to develop a picture of a male caller’s complaint:

- Advisor: Yeah? No shortness of breath or gasping for breath or anything?
 Patient: No.
 Advisor: No? Or any swelling to your mouth or your tongue or anything?
 Patient: Erm [1.5 second pause] no I don’t think so.
 Advisor: No. Okay. And so there’s no swelling anywhere to your face or anything?
 ...
 Advisor: But your face isn’t swollen or you know obviously=
 Patient: No.
 Advisor: =swollen or your arms or your legs you know obviously=
 Patient: No.
 Advisor: =swollen?
 (Equals signs indicate “latching” of turns, with no break in speech between speakers.)

As the extract shows, the healthcare advisor repeatedly makes use of *or*-conjunctions to chain together possible symptoms that the patient may be experiencing. These lists form the substantive part of interrogative clauses that require patients to evaluate their own condition against the listed symptoms. The use of conjunctions in this way serves several interactional purposes. First, by coordinating a number of possible symptoms which appear in related bodily areas—the mouth and face, the arms and legs—the health advisor can progress through the list of potential symptoms much faster than if each was asked in a discrete question, allowing more call time to be dedicated to subsequent advice-giving. Second, the syntactically coordinated symptoms consistently end with the use of the vague tag question “or anything?” which encourages the patient “to disclose symptoms which he or she might not otherwise have considered, nor thought relevant to the practitioner” (Adolphs et al., 2007, p. 67). This “symptoms plus vague tag” question structure creates a list of nonexclusive, nonexhaustive symptoms that guide callers to a particular part of their body and encourages them to offer any information that might be relevant. Rather than being interactionally insignificant, the use of the vague “or anything” in this context is highly valuable in eliciting all potentially salient information from the patient and thus conducting a thorough analysis of the ailment. Further, the placement of “or anything” as the conclusion of coordinated structure means that the potential symptoms represented by “anything” are syntactically equal to the more precise symptoms listed by the advisor, and thus are articulated as being of equal contextual importance. This combination of syntactic structure with vague language elegantly functions to involve patients in the interaction, prompting them to consider all possible symptoms and articulate anything they believe could be relevant.

The extracts also contain examples of the healthcare advisor using “you know.” This discourse marker functions outside of the main clause structure of the advisor’s utterances, and serves to negotiate the relationship between the professional and the caller. Specifically,

the use of “you know” immediately prior to “obviously swollen” indicates that the patient would be aware of what constitutes a swelling and, as with the psychiatric exit interview discussed above, foregrounds shared knowledge between speakers. Within the context of the clinical interaction, this also signifies that medical expertise does not rest solely with the healthcare advisor, as she indicates that the caller has some knowledge relevant to his own medical condition. Again, this serves to involve callers in the assessment of their symptoms, potentially eliciting relevant information that can substitute for the lack of proximity between patient and professional. Importantly, listener-oriented discourse markers such as “you know” also assist in generating a sense of rapport with the patient that helps reduce the imposition involved when the health advisor subsequently dispenses advice and instructs patients on additional ways to seek treatment. Establishing this concordant relationship also means the patient is more likely to follow a clinician’s prescriptions after the end of the encounter. For Western health services troubled by issues of patient compliance, creating a personable and trusting relationship with a patient is an increasingly salient aspect of a successful clinical encounter (Segal, 1994).

Conclusion

This entry has revealed the importance of seeing grammar as working in conjunction with, and being inseparable from, lexis. Indeed, it could even be argued that, following Hoey (2005, p. 1), grammar is an outcome of lexical arrangement. Whatever the case, the health communication routines examined above possess unique and recurring grammatical features that determine the course of such interactions. Although the grammatical interrogation was not exhaustive, with the focus limited to a selection of key syntactic features, the analysis revealed how healthcare professionals are able to marshal particular syntactic structures to help achieve immediate discursive goals, such as assessing patients, while also managing macro-level interpersonal relationships through discourse. The use of particular grammatical structures will vary between individual speakers and the tasks in which they are engaged. Nevertheless, grammar plays a significant interactional role in facilitating the provision of healthcare through patient–professional interaction.

Grammar and Electronic Communication

SUSAN C. HERRING

Introduction

How new digital communication technologies are affecting language and language change has excited considerable speculation and inspired a growing body of scholarship. At the heart of this question is the notion of grammar, or the set of structural rules that govern the composition of words, phrases, and sentences in a language. Language purists worry that electronic communication (also known as computer-mediated communication, or CMC) is corrupting the grammar of their language. The features of “Netspeak” (see below) are for the most part grammatical innovations, although scholars do not generally view their effects as detrimental.

To begin, grammar in electronic language must be understood somewhat differently from its usual sense as applied to speech. While the grammar of spoken language includes phonology, morphology, and syntax, in text-based CMC phonology is largely irrelevant; typography and orthography take over the functions of sound. Grammar in CMC also differs in that electronic language, as a new and still emergent phenomenon, has not yet had time (or attained the requisite social status) to become formalized in “rules”; rather, it exhibits patterns that vary according to technological and situational contexts (Herring, 2007).

This entry is primarily concerned to describe these patterns. Specifically, its focus is structural characteristics in text-based CMC at the utterance level (for an overview of discourse-level features, see Herring, 2001). It favors the English language, since most language-focused CMC research to date has analyzed English; however, a section on other languages is included. The structure of the lexicon is excluded, except insofar as it involves word formation processes that originated in CMC. Due to space constraints, the coverage is necessarily representative, rather than exhaustive, of the findings that have amassed since computer-mediated language first attracted research attention more than 25 years ago.

E-Grammar in English

As a convenience, the set of features that characterize the grammar of electronic language is referred to henceforth as *e-grammar*, although the use of this term is not intended to imply that there is a single grammar for all varieties of computer-mediated language. One linguist, David Crystal (2001/2006), has suggested as much (using the term “Netspeak” to refer to CMC as a single language variety), but considerable empirical evidence points to e-grammar as varying systematically across languages, contexts, users, and technological modes (e.g., Johanyak, 1997; Bieswanger, 2007; Herring, 2007).

The presentation that follows is organized according to the traditional hierarchy of grammatical phenomena in linguistics. It proceeds from the microlevels of typography and orthography, through morphology at the word level, to syntax at the utterance level.

Typography

In text-based CMC, typography refers primarily to the use of nonalphabetic keyboard symbols such as numbers, punctuation, and special symbols such as <, \$, and @. It also includes nonstandard capitalization (including ALL CAPS, lack of initial capitalization, alternating uPpEr AnD lOwEr case, and so-called “camel case,” or writing compound words or phrases together with MedialCapitals), as well as emoticons, or sequences of keyboard characters that prototypically imitate facial expressions (e.g., :-D and :-P represent a laughing face and a face sticking out its tongue, respectively). Western-style emoticons are viewed at a 90-degree angle, whereas Asian-style emoticons are viewed straight on, e.g., 0_o (a confused face) and <.< (eyes looking sideways); both types are used in English CMC. Emoticon use is widely claimed to be one of the defining typographical characteristics of electronic language (e.g., Crystal, 2001/2006), although studies of emoticons in English CMC report that they occur less often than popularly believed, that the overwhelming majority are simple “smilies” :-) or “winkies” ;-), and that emoticon use varies according to CMC mode and user gender (for an overview of emoticon research, see Dresner & Herring, 2010).

Other typographic characteristics of CMC include repeated punctuation (!!!, ?! . . .) and the substitution of numbers or letters for words or parts of words (e.g., 4 ‘for’, 2day ‘today’, ur gr8 ‘you’re great’). This latter usage is also sometimes classified as nonstandard spelling; indeed, there is considerable overlap between nonstandard typography and nonstandard orthography in CMC, and the two often co-occur.

Except for emoticons, which may be composed entirely of typographic symbols—and excluding as outside the scope of grammar drawings composed of keyboard characters, such as @|>--',--- to represent a rose (Werry, 1996)—the most conceptually extreme manipulation of typography in plain text English CMC is Leetspeak or Leet. In Leetspeak, some or all letters of a word are replaced by nonalphabetic symbols based on graphic resemblance; thus, Leet becomes 1337 or 133+, and @\$% is a common profanity. The name Leet comes from “elite,” and the style of writing originated among early Internet users as a kind of secret code, especially among hackers exchanging pirated files; it has since become popular in a number of online gaming communities. Some adepts claim it is a language variety with its own vocabulary, morphology, and grammar (Wikipedia, 2010a).

More common in CMC in general is the occasional replacement of words or parts of words with numbers or letters to save keystrokes, to symbolize a playful communication style or social identity, or to do both. Repeated punctuation is also common—although it makes messages longer, not shorter—to express affect (repeated letters, an orthographic strategy, functions similarly). Such nonstandard typography is especially common in short message service text messaging (SMS), where the message buffer is limited to 160 characters, followed by synchronous CMC modes such as chat and instant messaging (IM), in which exchanges are typically rapid and social in nature; it is also found in e-mail, even in professional contexts (Murray, 2000; Anis, 2007; Cho, 2010).

Orthography

Nonstandard orthography is widely considered to be a defining characteristic of computer-mediated language, and indeed, e-communication often manifests spelling practices that suggest loosened orthographic norms. These include abbreviation (acronyms, clippings, vowel omission as in *pls* for ‘please’, etc.); phonetically motivated letter substitutions (e.g., z for ‘s’); spellings that imitate casual or dialectal pronunciations (e.g., *wassup?* for ‘what’s up?’); eye dialect (e.g., *sez* for ‘says’); and spellings that represent prosody or nonlinguistic sounds, such as a “calling voice” (*helloooo*), laughter, and other (nonhuman) noises.

Language prescriptivists typically view such practices as misspellings or errors (Thurlow, 2006). In fact, the proportion of nonstandard spellings that are unintentional is very low among native speakers. Abbreviations save keystrokes, as do some phonetic spellings, and representing speech in writing is a manifestation of the “orality” of much text-based CMC (e.g., Cho, 2010). Moreover, representations of nonlanguage sounds enrich CMC in the absence of auditory cues. These representations often accompany other kinds of textual performance, including indications of actions, for which an entire set of orthographic/typographic conventions has developed, such as *w* for a wink (e.g., Werry, 1996; Cherny, 1999).

Early studies such as Cherny’s and Werry’s emphasized the playfulness and creativity driving these phenomena, especially in recreational chat environments. However, recent research suggests that a relatively small number of nonstandard spellings (e.g., *u* ‘you’, *msg* ‘message’, *wanna* ‘want to’) have become conventionalized and occur most often in mainstream online contexts, while unique formations are less common (Kapidzic, 2010).

A counterexample to this trend is “lolspeak,” the fractured text that accompanies images of “lolcats,” which were popularized on the Internet several years ago by a photograph of a cat captioned *I can has cheezburger?* Lolspeak remains popular in the image forums where it originated, and it is sometimes used (minus images) for humorous effect in other CMC contexts, including Facebook status updates. Another counterexample is the language use of fans of the character “Ali G,” as created by the (White) British comedian Sacha Baron Cohen, on Web sites and discussion boards; fans imitate Ali G’s spoken style, which is a mix of Jamaican Creole and Southern British English street language, through creative spelling and unconventional grammar and lexis (Sebba, 2007). Like Leetspeak, these cases represent special registers in which a concept (replacement of letters with other symbols; cats’ imaginary “bad English”; a comedian’s humorous language style) generates unbridled orthographic (as well as morphological and syntactic) creativity.

Morphology

Relatively few descriptions of computer-mediated language mention morphology. Those that do mainly note the emergence of a few productive word formatives (e.g., *e-*, *cyber-*, *hyper-*) and the outcomes of word formation processes such as clipping (e.g., *nick* from ‘nickname’), blending (e.g., *netizen* from ‘network citizen’), acronyms (e.g., *lol* ‘laugh out loud’, *jk* ‘just kidding’, *OMG* ‘oh my god’, *wtf* ‘what the fuck’), semantic shift (e.g., *flame* ‘unleash invective on a computer network’, from *flame* ‘to act conspicuously homosexual’; *spam* ‘Internet junk mail’, from *spam* ‘a type of canned meat’), and conversion from one part of speech to another (e.g., *text* as a verb; *spam* as a verb). These processes are not unique to CMC, but they have been especially productive on the Internet, generating many new words that are increasingly making their way into dictionaries of Standard English.

Less commonly attested word formation processes include outright neologisms, such as *newbie* (sometimes clipped to *noob* or *n00b*, ‘an inexperienced person’), and conventionalization of frequently occurring typographical errors, such as *teh* (‘the’). Leetspeak claims both of these, along with several productive derivational and inflectional suffixes, including *-age* (e.g., *flamage*, from the verb ‘flame’), *-zor* (parallel to Standard English *-er/-or*), and *-zorz* (which intensifies the meaning of a verb, as in *pwnzorz* ‘really defeat’, from *pwn*, itself a conventionalized misspelling of the word ‘own’). These suffixes are not in general use.

The most creative examples of e-morphology have been reported in playful, self-contained contexts, for example in a multiplayer online game (MOG) (Nilsson, 2009); in a social MUD (multi-user dimension), a type of text-based virtual world (Cherny, 1999); and in e-mails exchanged in a private sibling code (Rowe, in press). MOGs, in which interaction can be intense and fast-paced, generate numerous acronyms and shortened forms specific to the

game context, e.g., *gg* ('good game'), *wtb* ('want to buy'), and *lol* ('level'). Examples from the social MUD, which Cherny describes as a relatively closed community of computer geeks, include the productive derivation of verbs from interjections (e.g., *Mike cools*, meaning 'Mike says "cool"') and verb reduplication (e.g., *nods nods*) to indicate a repeated or emphatic action. The sibling code, which originated between two sisters in childhood but increased in use when they started e-mailing as adults, produced such novel words as the clipping *immuze* ('immunizations') and *fibin'* (acting like a type 'five' (*fibe*), i.e., avoiding), which involves both semantic shift (from 5 as a numeral to 5 as a personality type) and conversion (from a noun to a verb).

As these examples illustrate, more than one morphological process may operate on a single word, and unconventional morphology sometimes combines with unorthodox typography and/or orthography.

Syntax

The syntax of computer-mediated English, when it deviates from standard syntax, is sometimes described as "telegraphic" and fragmented. Parts of speech such as articles and subject pronouns may be elided in informal style, and messages that do not contain a complete grammatical clause (with a subject and finite predicate) are common, especially in CMC modes characterized by brief, informal messages, such as chat, IM, SMS, and microblogging. The usual reason given for elision is to save keystrokes (e.g., Murray, 2000), whereas sentence fragments may be caused by people typing speech-like utterances; or by the requirement in some CMC systems that messages be brief, which can lead users to break longer utterances into several messages (e.g., Baron, 2010); or by both.

CMC syntax also diverges from the standard when users attempt to represent a non-standard language variety, such as African American Vernacular English (often via copula deletion or invariant 'be') or Ali G's fractured style (Sebba, 2007). Moreover, special registers of CMC sometimes evolve productive syntactic strategies not found in other CMC modes, such as preposition deletion in the MUD register described by Cherny (e.g., *John laughs Lynn*), the double-inflected-modal *can haz* construction in lolpeak, and nominalization of verbal predicates for emphasis in Leet (e.g., *Au5t1N is t3h r0xx0rz*, literally 'Austin is the rocks-er', meaning 'Austin really rocks'; Wikipedia, 2010a).

A syntactic innovation particular to CMC environments is third person singular present tense performative utterances, also called "emotes." Emotes are commands that cause the user to perform a social action by logging a description of that action into a chat window; in a MUD, for example, when Kim types *"/waves,"* the message *Kim waves* is displayed (Cherny, 1999). Emotes started as pre-programmed shortcuts in online game environments, where they are still popular. Until recently, Facebook promoted the use of similar-looking third person present tense utterances by providing the default prompt *[Username] is . . .* for first person status updates. Both systems sometimes give rise to inconsistent pronoun and tense usage, as in *Susan waves goodbye and puts on my hat* and *Jim Cosmo is just saw a meteorite*. For the most part, however, such mixed constructions are assumed to be unintentional and (at least mildly) infelicitous.

Related to emotes are predications that can function alone as complete performative utterances, such as **waves**, *<grin>*, **confused**, and **in a bad mood**. Semantically, such "performative predications" may involve virtual actions or states. Structurally, they may be inflected or uninflected, and they are often set off by typographic brackets. Rather than being pre-programmed, they are typed out by the user, although a number are highly conventionalized. A common type expresses vocalizations, such as **sigh(s)/sob(s)/laugh(s)/lol(s)**, that could also be expressed via typed representations of sound (e.g., *hahaha*) or emoticons. Note that the acronym *lol* may be inflected like a verb; it may also represent a

pulse of laughter (*lololol*) or be spelled as it is pronounced (e.g., *lawl*, *lulz*), or both, especially in teen chat (Kapidzic, 2010). Most popular in social chat environments, where they originated, performative predication are also common in other CMC modes.

Many researchers have measured the frequency of grammatical function words, such as pronouns, determiners, modal auxiliaries, and negation, in electronic corpora. CMC can be distinguished from traditional genres of speech and writing according to these measures; typically it falls between the two extremes, with synchronous chat closer to casual speech and asynchronous modes such as e-mail closer to formal writing (e.g., Ko, 1996; Yates, 1996). Correlations have also been reported between frequency of grammatical markers and nonlinguistic phenomena, such as lying in CMC (e.g., Hancock, Curry, Goorha, & Woodworth, 2008), gender of blog authors (Herring & Paolillo, 2006), and bloggers' psychological response to trauma (Cohn, Mehl, & Pennebaker, 2004).

E-Grammar in Other Languages

Structural features of CMC in languages other than English have been less studied (see Danet & Herring, 2007), although this varies by language: German CMC, for example, has received considerable attention (in German), and the typography and orthography of French CMC have been described in several works by the late Jacques Anis (in French). At the other extreme, the structure of many languages used online remains virtually undescribed (e.g., Russian, Korean, African languages), at least in venues accessible to Western readers. Furthermore, typography and orthography have been better described than morphology and syntax, and some languages raise issues (such as code mixing) that blur these levels of analysis. Nonetheless, several general findings can be noted.

First, contrary to Crystal's (2001/2006) claim, "Netspeak" is not universal. While there is ample evidence that CMC users in other languages play with typography and orthography (see, e.g., Nishimura, 2003 for Japanese Web boards; Anis, 2007 for French SMS; Herring & Zelenkauskaitė, 2009 for Italian SMS); different strategies are favored in different languages and used in different proportions, as Bieswanger (2007) demonstrated through a systematic comparison of English and German SMS.

Second, and relatedly, languages that make use of non-Roman writing systems have often had to use ASCII (plain text) in CMC environments (although this is changing due to Unicode and programs that convert QWERTY keyboard symbols to characters in other languages), requiring creative adaptation (Danet & Herring, 2007). Some languages exhibit both sound-based and graphic-based character substitutions. For instance, the Greek letter theta is written in plain text CMC both as "th" (representing its sound) and as "8" (approximating its appearance in the Greek alphabet) (Tseliga, 2007; for an analogous practice in Arabic, see Palfreyman & al Khalil, 2003). These Romanized forms may in turn create new language varieties, as in the case of "Greeklish," which in addition to being written in the Roman alphabet is characterized by less sentence-initial capitalization, more emoticons, and more English borrowings (e.g., "message," "pc," "sorry," "sex") than Greek written in the Greek alphabet (Tseliga, 2007).

This leads to the third observation, which is that English influences other languages used online, through borrowing of computer-related terms and e-grammar conventions. Lee (2007) found, for instance, that Cantonese in Hong Kong dyadic chat, which is written in a mix of Romanization and Cantonese and Mandarin characters, includes many English "Netspeak" features, along with the use of numerals to represent sounds (e.g., 99 'nighty night' in Chinese English pronunciation). Code mixing of a local language with English or another regional lingua franca occurs often in bi- and multilingual environments. For example, in Web forums and chatrooms for Greeks, Turks, and Persians living in Germany,

mixing of the native languages and German takes place on multiple linguistic levels: lexical, phrasal, propositional, and discourse-pragmatic (Androutsopoulos, 2007a).

English is not the only language with special online registers. German rappers post messages on Web forums in which they imitate “hiphop speech” in a mix of German and English (Androutsopoulos, 2007b). Russian *padonki* (an intentional misspelling of *podonki* ‘riff-raff’, ‘scum’) is a subcultural phenomenon reminiscent of lolspeak, characterized by erratic spellings and gratuitous use of profanity for comic effect (Wikipedia, 2010b). The *Fakatsa* style popular among Israeli girl bloggers, which replaces Hebrew letters with graphically similar numbers and Roman letters, somewhat resembles Leetspeak (Vaisman, in press).

Nonstandard language use online poses problems for machine translation. Climent et al. (2003) found this to be true even in academic newsgroup postings in two structurally similar languages, Catalan and Spanish. The available research suggests that structural irregularities are prevalent in CMC, even if for the most part e-grammar adheres to standard language norms (see Thurlow, 2006).

E-Grammar and Language Change

More than 25 years ago, Baron (1984) predicted that the Internet would change language for the worse. More recently, Stein (2006) predicted that it would accelerate the rate of language change. What limited diachronic studies of online language are available suggest that e-grammar tends to become, if anything, more standard over time (e.g., Herring, 1998), but that in subcultural and interpersonal contexts of intensive, self-contained interaction, such as the private sibling code analyzed by Rowe (in press), e-grammar may evolve at an accelerated pace.

Many e-grammar innovations have been adopted by the wider community of Internet users. Features such as emoticons and certain acronyms and spellings have been taken up across the Internet, including being borrowed into other languages’ CMC. Others, such as emotes and “performative predicates,” have also extended productively beyond their source contexts. Even features of special registers such as Leet, lolspeak, and online rapper language are attested outside their source contexts, although such usage is often tied referentially to its original contexts of use.

The evidence is less clear as regards the diffusion of e-grammar into language use offline and into languages themselves, as codified in grammars and dictionaries. Dictionaries are certainly including more CMC and computer-related terms all the time. Yet evidence of the spread of other CMC practices to a language as a whole tends to be anecdotal. Several years ago, National Public Radio in the USA broadcast a segment about teens speaking “Netspeak” abbreviations (e.g., pronouncing *lol* as /lawl/ and *I <3 u* as ‘I heart you’). Marketers sometimes use nonstandard online forms, including from lolspeak and padonki, in billboards and advertisements (see, e.g., Wikipedia, 2010b). Such uses seem humorous, however, and self-consciously Internet referential.

At the same time, self-report studies indicate that young people are increasingly using e-grammar in their offline writing (e.g., Pew Internet & American Life Project, 2009). Rather than this causing a decline in young people’s language skills, Plester, Wood, and Joshi (2009) found that greater knowledge of SMS abbreviations was associated with higher word reading, vocabulary, and phonological awareness measures. While this research is limited, and many gaps remain, it suggests that language change is being affected and effected by Internet communication, and that if anything, e-grammar enriches rather than impoverishes language users and languages themselves.

Grammar and Literature

NINA NØRGAARD

At its most basic level, literature is language. Through language, literary texts represent—or rather construct—characters, settings, plots, experiences, feelings, and ideas, and while linguistic knowledge is by no means a prerequisite for the analysis of literature, such knowledge may help the literary critic understand and describe the ways in which meaning is created by linguistic means in literary texts.

Academic interest in the grammar of literature basically started with the Russian Formalists in the early 20th century, gained momentum in the 1960s and early 1970s, and developed into what is now known as “stylistics,” or sometimes more specifically as “literary stylistics” or “literary linguistics.” Stylisticians explore the application of linguistic frameworks and methodologies to the description and analysis of literature as well as other types of text such as advertising, political oratory, legal documents, different types of media discourse, academic writing, etc. The texts put up for analysis are typically examined with respect to their phonological, lexical, grammatical, semantic, pragmatic, or discoursal features, or, as is quite often the case, with respect to various combinations of these.

Along with developments in modern linguistics, the study of the grammar of literature has branched off into various specialized subfields. As a consequence of this, modern stylistics has grown into a varied landscape of subbranches such as historical stylistics, cognitive stylistics, corpus stylistics, pragmatic stylistics, and others which are based on, inspired by, and sometimes also suggesting adjustments to the linguistic paradigms from which they spring. Other branches are oriented toward context in some respect. An example of this is feminist stylistics, which is concerned with the linguistic manifestation of gender relations in text. In spite of the different concerns and foci of the different branches, a common denominator for all is a central interest in the linguistic “how” of meaning making, that is, in how meaning is created by linguistic means.

Stylistics is often described as a “tool box” or “tool kit” consisting of linguistic concepts and methods that literary critics may employ for linguistic substantiation of their analysis of literature. While some stylisticians may limit their choice of “tools” to one compartment of the stylistic tool box according to the linguistic orientation of their approach, others may be more eclectic and choose more freely among all the tools available.

Formalist Stylistics

Characteristic of much of the early work done on the grammar of literature was an overriding concern with form. The Russian Formalists wished to qualify the analysis of literary texts by basing such analysis firmly on concrete observations about the formal grammatical features of the texts in question. They were particularly interested in poetic form, or “literariness” (see Jakobson, 1960), and focused primarily on the formal features that made a text poetic and set it apart from other types of text. According to Jakobson (1960), the poetic function of language is dominant in texts that “focus on the message for its own sake.” “Message” here equals wording and grammar, and texts which are marked as poetic

are consequently those whose phonological, lexical, and grammatical choices draw attention to themselves and thereby to the literariness of the text or passage in which they occur. Parallelism and deviation from the linguistic norm are examples of formal features which were seen to mark a text as poetic, and poetry was the text type favored for analysis.

When the interest in the grammar of literature gained a foothold outside Eastern Europe in the 1960s and early 1970s—most prominently in Britain and the United States—stylisticians were much influenced by the work done by the Russian Formalists and members of the Prague School of Linguistics. The focus on grammatical form and structure was largely continued, as was the interest in texts which displayed a high degree of literariness. Critics, in turn, saw these early stylistic studies as mechanical descriptions of grammatical form which were far detached from relevant interpretation, and furthermore accused the formalist approach of ignoring the social, historical, and pragmatic contexts of the passages and texts put up for examination (e.g., Weber, 1996, p. 2). Notwithstanding these alleged weaknesses, the formalists clearly laid the foundations of stylistics in various respects, in particular by their insistence on anchoring the analysis of literature solidly in the actual grammar and lexis of the text, and by the consistent, systematic nature of their approach.

Functionalist Stylistics

As a reaction to the formalist focus on grammatical form and detachment of language from context, many stylisticians in the late 1970s and onwards turned to newly emerging linguistic paradigms whose main concern was with grammatical function and the social role of language. Most influential among these in stylistics was Michael Halliday's *Systemic Functional Linguistics* (Halliday, 1994). Halliday gives emphasis to the social function of language in use and the consequent necessity of examining language in context, and furthermore privileges semantic function over grammatical form. The Hallidayan approach is characterized by linguistic constructivism, that is, the belief that language does not neutrally represent meaning, but actively constructs, or "construes" it. It furthermore privileges the text, rather than the sentence, as the main unit of description, which makes it a useful tool for those interested in analyzing the grammar of more extensive pieces of literature such as the novel and play texts.

It is central to the Hallidayan model of language that language use is claimed to simultaneously express ideational (alternatively: experiential) meaning (to do with the linguistic representation of experience), interpersonal meaning (to do with the relations between interlocutors), and textual meaning (relating to the linguistic organization of text). The model provides a functionally oriented descriptive grammatical apparatus for the three types of meaning, which is employed in literary stylistics for examinations of the ways in which literary characters, actions, settings, etc. are constructed ideationally, interpersonally, and textually by linguistic means (Toolan, 1998; Nørgaard, 2003). A good example of this is provided by Kennedy (1982) in an analysis of ideational meaning in the passage from Joseph Conrad's *The Secret Agent* (1907) where Mrs. Verloc kills her husband. Ideational meaning concerns the way the world is represented, or constructed, linguistically in terms of configurations of participants, processes, and circumstances. In his analysis, Kennedy demonstrates how Mr. Verloc, by being represented as the participant of mental processes of perception ("heard," "saw," "take in") and intransitive material action processes which do not extend to other participants ("waited," "was lying," "expired"), is constructed as a passive observer of his own death. Mrs. Verloc, on the other hand, is constructed as somehow detached from the act of killing she performs, since parts of her body and the knife with which she kills her husband are represented as the active participants (or agents) of the deed, as exemplified by the following sentence: "Her right hand skimmed

lightly the end of the table, and when she had passed towards the sofa the carving knife had vanished without the slightest sound from the side of the dish" (Conrad in Kennedy, 1982, p. 86).

The emphasis given to linguistic constructivism and context by the functional approach to language furthermore opened the way for new branches of stylistics with a pronounced contextual slant. One such approach is that taken in feminist stylistics, which focuses on the linguistic manifestation of (unequal) gender relations in literary as well as nonliterary texts. From a feminist perspective, Burton (1982), for instance, demonstrates how the female protagonist of Sylvia Plath's *The Bell Jar* (1963) is constructed as passive and powerless by linguistic means. Critical stylistics is another approach to the grammar of literature which focuses on linguistic constructivism more generally, examining how inequality, power structures, and ideology are expressed and maintained by different texts (Fowler, 1986; Simpson, 1993; Jeffries, 2010).

Cognitive Stylistics

Another branch of stylistics, which has grown very strong since its emergence in the early 1990s, is that of cognitive stylistics. Following developments within the linguistic paradigm of cognitive linguistics and related fields such as blending theory and conceptual metaphor theory, cognitive stylistics aims to combine "the kind of explicit, rigorous and detailed linguistic analysis of literary texts that is typical of the stylistics tradition with a systematic and theoretically informed consideration of the cognitive structures and processes that underlie the production and reception of language" (Semino & Culpeper, 2002, p. ix). Cognitive stylisticians are thus concerned with the reader's conceptualization of the text in the process of reading with particular emphasis given to the linguistic aspects of the text that prompt particular conceptualizations. Meaning is thus not considered to reside in the text alone, but is regarded as a dynamic product of the text and the reader's mental processing of it. In the analysis of literature, it is also considered, for instance, how the linguistic construction of a character's "mind style" (see Fowler, 1986) reflects how this character perceives the world around him or her. In an analysis of John Fowles's *The Collector* (1963), Semino (2008) examines how the male protagonist, Clegg, who is a butterfly collector, conceives of the young woman, Miranda, whom he kidnaps, in terms of a butterfly. Through this "conceptual metaphor," meanings related to butterflies (the so-called "source domain") are "mapped" onto Miranda (the "target domain"), and, according to Semino (2008, p. 272), "the BUTTERFLY metaphor does not simply affect Clegg's language and thoughts, but also guides his actions." At the same time, Clegg's use of the butterfly metaphor and its concrete linguistic realization in the novel furthermore function as linguistic triggers which govern the reader's conceptualization of Clegg and his thoughts and actions. The references to butterflies and butterfly collectors activate the reader's background knowledge of such phenomena, which thereby comes to play a role in the meaning created in the reader's processing of the text.

Corpus Stylistics

With the rapid advances in computer technology, the computer has seriously entered the field of stylistics as a tool for those who wish to base their examination of the grammar of literature solidly on large amounts of empirical data. Where, previously, stylistic analysis had to be done manually, computer software now enables the analyst to perform quantitative investigations of linguistic phenomena in very long texts, such as the novel, or even in all the novels of a particular writer, several novels from a particular decade or

century, and so forth. Corpus methods can, of course, also be employed for the analysis of shorter texts. Often, the text put up for examination is measured against a reference corpus of similar types of text in order to detect both conventional and more unconventional patterns of lexis and grammar in the text examined. In an analysis of Joseph Conrad's *Heart of Darkness* (1902), Stubbs (2008), for example, employs corpus stylistic methods to qualify the claims by more traditional literary studies of the text that a number of content words such as "fog," "mist," "vague," and "indistinct" support the novel's general theme of vagueness and uncertainty. Running the text through relevant computer software reveals, for instance, how these lexical items are actually part of a much larger group of related words, a so-called "lexical field": "blurred," "dark/ly/ness," "dusk," "fog," "gloom/y," "haze," "mist/y," "murky," "shadow/y," "shade," "shape/s/d," "smoke," "vapour." This observation is supported by a search for grammatical words which likewise express vagueness and uncertainty: "something," "somebody," "somewhere," "somehow," "some," "like" (as preposition), "kind of," "sort of," as well as for the verb "seemed." When comparing these findings against two reference corpora of respectively a large corpus of fiction and an even larger written corpus, Stubbs finds that the frequencies of these words in Conrad's novel are considerably higher than in the two other corpora. While acknowledging the limitations of such word frequency lists, Stubbs nevertheless argues that "there must be some relation between frequent vocabulary and content, and frequency lists are one essential starting point for a systematic textual analysis" (2008, p. 234). To further qualify his analysis, he backs it up with an examination of collocation, that is, of words that occur together in more than regular frequency and thereby create certain connotations, as, for example, "grass [which] is usually associated with death, decay and desolation" (Stubbs, 2008, p. 237). Finally, Stubbs's corpus stylistic examination of *Heart of Darkness* also reveals a high frequency of words with negative prefixes: "impossible/ity," "uneasy/iness," "unexpected/ness," "impenetrable," "inconceivable/ly," "incredible," "indistinct/ly," "intolerable/ly," "unknown," "incomprehensible," "inscrutable," "unearthly," and "unsound." Based on linguistic knowledge that negative constructions often imply that the positive was expected, he interprets the extensive use of negatives by Conrad in the following way: "the frequent negatives represent a world which is strange, foreign, alien, contrary to cultural expectations" (Stubbs, 2008, p. 239). While some are worried that the corpus approach to the language of literature will fail to capture the special nature of literary art, others, like Stubbs, see this approach as a useful tool for handling large amounts of literary-linguistic data and for empirically testing the analyst's intuitions about the text.

Multimodal Stylistics

One of the most recent developments in stylistics is the growth of interest in what is referred to as "multimodal stylistics." Proponents of this branch of stylistics aim to extend the stylistic tool kit with analytical tools that will allow equally systematic analyses of texts which, in addition to wording, make use of further semiotic modes such as typography, color, layout, and visual images for their construction of meaning. To that end, multimodal stylisticians draw on various approaches to multimodality, most prominent among them that of Kress and van Leeuwen (1996, 2001), Baldry and Thibault (2005), Forceville (1996), and others, who have set out to develop "grammars" for different semiotic modes and their multimodal interaction in communication. In *Reading Images: The Grammar of Visual Design* (1996), for example, Kress and van Leeuwen sketch out a grammar for visual images and page design which—with a base in Hallidayan linguistics—demonstrates how visual modes, like the verbal, create ideational, interpersonal, and textual (or "compositional") meanings. From a cognitive perspective, scholars such as Forceville (1996) and Currie

(2004) investigate multimodality in respectively advertising and film, yet the cognitive approach to multimodality can also be applied in the analysis of literary texts (e.g., Gibbons, 2010). When analyzing the grammar of literature, multimodal stylisticians hence operate with an extended notion of “text” which in addition to the verbal comprises a range of different semiotic modes. Even the most conventional literary text is perceived as multimodal, since printed verbal language always automatically involves modes such as typography, layout, and color. The extended multimodal stylistic tool box furthermore allows the analyst to handle more experimental literature such as Jonathan Safran Foer’s *Extremely Loud and Incredibly Close* (2005), which employs elements such as visual images and color as well as special typography and layout for its meaning making. In addition to this, the multimodal approach also enables more comprehensive stylistic analysis of the novel, for instance, since it provides grammatical tools for describing the way meaning is created by paratextual elements such as the book cover and other aspects of the novel’s material realization (Nørgaard, 2010).

Concluding Remarks

Even if some of the early proponents of stylistics aimed to make the analysis of literature more objective and “scientific” than more traditional literary criticism by basing their analysis on linguistic theory and methodology, it should be noted that no analysis can ever be objective; not even that which is anchored solidly in the lexis and grammar of the text. Like all other types of analysis, the analysis which focuses on the grammar of literature will necessarily be colored by factors such as the analyst’s individual intuitions, preferences, and foci as well as the linguistic/stylistic paradigm and methodology employed. In spite of this reservation, the application of linguistic theory and methodology (ideally) ensures informed, rigorous, and systematic analysis which is based firmly on the actual wording of the text, and furthermore provides the analyst with a consistent metalanguage by means of which the analysis can be conducted.

Stylistics is now an established field of research with its own journals and international associations. The Poetics and Linguistics Association (PALA) and the International Association of Literary Semantics (IALS) are currently the most prominent academic associations in the field, while *Language and Literature* (<http://lal.sagepub.com/>), *Journal of Literary Semantics* (www.degruyter.de/journals/jls), and *Style* (www.style.niu.edu) are relevant journals to consult for those with an interest in the interface of language and literature. Due to its interdisciplinary nature, the focus on the grammar of literature as well as other types of text has furthermore gained a place in education, where courses in stylistics aim to improve students’ analytical and practical skills at a linguistic level, while at the same time making more explicit the link between linguistic and literary disciplines of various language degrees.

Grammar and Social Class

RONALD MACAULAY

Both terms in this title are problematic. Grammar is sometimes used in a very broad sense, as when Chomsky (1965, p. 4) says that the grammar of a language “purports to be a description of the ideal speaker-hearer’s intrinsic competence.” In this sense, the notion of grammar includes semantics, syntax, morphology, phonology, and phonetics. In contrast, Cheshire and Edwards (1993, p. 35) report on “a survey of British dialect grammar” in which their “aim was to obtain information on dialect syntax.” Their notion of syntax, however, includes morphology, as do other contributions to Milroy and Milroy (1993), whose work is subtitled *The Grammar of English Dialects in the British Isles*. The emphasis in the present entry is on grammar interpreted narrowly as syntax.

Social class remains a controversial subject despite attention from a number of scholars in recent years. No clear method of identifying social-class membership has appeared. As Gilbert observes, “there is as much art as science in the study of social stratification” (2003, p. 16). This complicates the question of social-class differences in language, since different investigators have employed different methods of determining social-class divisions. Some have treated social class as a continuum and divided it into categories on the basis of certain criteria. Other investigators have treated social class as a dichotomy with two polarized categories, and still others have used several discrete social-class divisions. These differences in approach are likely to be problematic only if there are conflicting results from sociolinguistic investigations of similar situations. In what follows, social-class differences will be examined only with respect to differences between middle-class and working-class speech in Britain because this is the situation that has been investigated most fully.

The greatest problem, however, is that there has been very little investigation of variation in syntax. Most sociolinguists dealing with social-class differences have concentrated on phonological and (less frequently) morphological variables. Some of the reluctance probably followed from Lavandera’s (1978) observation that syntactic differences were different from phonological and morphological variables because the variants could not be considered semantically identical. One consequence of this is that a different approach is necessary for studying syntactic variation. There is also the major problem that studying syntactic variation requires larger and more varied samples of speech than are needed for phonological and morphological variables.

The problem of investigating social-class differences in syntax is further confounded by the lack of evidence on spoken syntax. As Cheshire and Stein (1997, p. 2) observe, “there is a sorry lack of empirical data on the syntax of speech.” It has often been pointed out that syntactic analyses based on a speaker’s intuition are dependent on the norms of written language and provide no direct evidence of how people actually speak. The codification found in dictionaries reinforces the identification of the standard language with the written form. Thus there is a danger that spoken forms will be labeled nonstandard on the basis of their difference from written norms. What is needed for the examination of class differences in grammar is a data set from a stratified sample of speakers who have equal opportunities to express themselves in an unconstrained situation for a sufficient period of time to allow them to use a variety of syntactic expressions. In the absence of categorical differences, the measure of variation will be frequency of use.

The pioneer in the empirical study of social-class differences in linguistic features other than pronunciation was Bernstein (1959, 1962). Bernstein's insight was to set out a number of testable hypotheses about social-class differences in speech. He reported the results of recording sessions with groups of 10 middle-class and 14 working-class boys aged 15 to 18, discussing the abolition of capital punishment. Bernstein's methodology was totally inadequate and contaminates his results (Macaulay, 2005, p. 43), but for many years his findings received serious consideration.

Bernstein claimed that the working-class boys used more of what he calls "sympathetic circularity markers" (1971, p. 97 [1962, p. 223]), including discourse markers such as *you know* and tags such as *isn't it*, *ain't it*, and *wouldn't he*. His figures for sympathetic circularity sequences convert to frequencies of 2.53 per 1,000 words for the middle-class boys and 14.14 per 1,000 words for the working-class boys. He also found that the middle-class boys used *I think* more frequently than the working-class boys, whereas the latter used the sequence *I mean* twice as frequently. Bernstein excluded *I mean* from the analysis "as it was considered a simple reinforcing unit of the previous or subsequent sequence and likely to be an idiosyncratic speech habit" (1971, p. 98 [1962, p. 224]).

Bernstein also developed measures of subordination, complexity of the verbal stem, and use of the passive. In all cases the middle-class boys scored significantly higher than the working-class boys. Bernstein found that the middle-class boys used significantly more "uncommon adverbs" and "uncommon adjectives." Finally, Bernstein found that the middle-class boys used fewer personal pronouns overall but used the pronoun *I* more frequently than the working-class boys did.

Macaulay (1991) provides comparable evidence of social-class differences in a stratified sample of speakers in Ayr, Scotland. Six middle-class and six working-class adults were interviewed by the same interviewer. The interviews were transcribed in their entirety and stored as computerized texts. Each line of the transcript was coded according to 49 different syntactic categories. Consistent with Bernstein's findings, the middle-class speakers did in fact "exhibit a greater use of subordination in general and a more frequent use of subordinate noun clauses in particular" (Macaulay, 1991, p. 106), but there were no clear social-class differences in the use of passives. In some cases the differences were slight and no tests for statistical significance were carried out.

Contrary to Bernstein's finding, the middle-class speakers used *you know* (2.1 per 1,000 words) almost as frequently as the working-class speakers (2.3 per 1,000 words; Macaulay, 1991, p. 145). However, Bernstein's observations on adverbs were fully supported. The middle-class speakers used derived adverbs ending in *-ly* with a frequency of 8.9 per 1,000 words compared with a frequency of 2.6 per 1,000 words in the working-class interviews.

Several investigators have reported on social-class differences in the use of *you know*. Dines (1980, p. 16) reports that two unpublished Australian studies, Poole (1973) and Brotherton (1976), found "a higher frequency of *you know* in lower-working-class speech," but does not give more details. Huspek (1989, p. 665) found *you know* to be frequent in the speech of the workers he interviewed but he did not interview middle-class speakers, so there are no comparative figures. Stubbe and Holmes (1995) found *you know* to be significantly higher in working-class speech in New Zealand, though they admit that in New Zealand research "social class divisions are fluid and the concept must be used with caution" (1995, p. 67). Woods (1991, pp. 146–7) found the use of phrases signaling sympathetic circularity to be significantly more frequent in working-class speech but he also reports "that the percentage of speakers who use signals of sympathetic circularity is high in all social classes" (1991, p. 146).

In 1997, Stuart-Smith recorded a stratified sample of 17 adults and 16 adolescents in Glasgow (Stuart-Smith, 1999). Participants were asked to choose a friend or acquaintance with whom they would be willing to talk for half an hour in the presence of a tape recorder,

without the investigator being present. The sample was balanced by age (adolescents 13–14 and adults 40+), social class (middle class and working class), and gender. The tapes were transcribed in their entirety and provided evidence for the analysis of a number of syntactic and discourse features (Macaulay, 2005).

As in Ayr, there were no significant differences in the use of *you know* by middle-class speakers (3.29 per 1,000 words) and working-class speakers (3.49 per 1,000 words; Macaulay 2005, p. 66) but there were differences as to where the sequence occurred in the clause. In the middle-class conversations 50% of instances occurred in medial position in the clause and 32% in final position. The working-class speakers used *you know* predominantly in final position (65%) and only 10% used it in medial position (Macaulay, 2005, p. 69). The latter figures are for the adults only as the adolescents seldom used *you know* (0.86 per 1,000 words).

In contrast to the results from Ayr, both the middle-class adults and the adolescents in Glasgow use the passive significantly ($p < .05$) more than the working-class speakers. The frequency for the middle-class adults was 3.06 per 1,000 words compared with 1.77 for the working-class speakers. The figure for the middle-class adolescents was 3.01 compared with 2.70 for the working-class adolescents. The adolescents had a higher proportion of *get*-passives. The Glasgow working-class adults used modal auxiliaries more frequently (17.84 per 1,000 words) than the middle-class adults (11.64 per 1,000 words, $p < .02$). There were no social-class differences in the use of modals in the Glasgow adolescent conversations or the Ayr interviews.

Although he was not able to establish this in his 1962 empirical study, Bernstein had earlier characterized what he was then calling a public language (the form used by “the unskilled and semi-skilled strata”) as employing “short, grammatically simple, often unfinished sentences, a poor syntactical construction with a verbal form stressing the active mood” (Bernstein, 1971, p. 42). Bernstein here seems to be confusing speech with writing. Short, syntactically simple clauses are characteristic of impromptu speech, in which the passive voice is rare. Most of the clauses in the Glasgow conversations contain a single finite verb (85% for the adults and 93% for the adolescents). There are no social-class differences among the adults but for the middle-class adolescents the proportion is 86% compared with 99% for the working-class adolescents. It is not always noted that Bernstein’s results are based solely on the speech samples of adolescent boys.

One set of constructions—dislocated syntax—is used more frequently by working-class speakers both in Ayr and in Glasgow: demonstrative focusing (“and that was you shut in the house for a week”), clefting (“it’s them that’s running it now”), noun-phrase preposing (“an auld auld man he was you ken”), left dislocation (“Mr Patterson he was a gentleman”), and right dislocation (“she was a very quiet woman my mother”; Macaulay, 2005, pp. 93–5). The working-class speakers in both Ayr and Glasgow used these constructions significantly more frequently ($p < .001$) than the middle-class speakers did. These constructions are obviously more complex than simple SVO clauses, which is contrary to Bernstein’s claim.

As in Ayr, there were significant social-class differences in the use of derived adverbs ending in *-ly*. The middle-class speakers used such adverbs with a frequency of 11.89 per 1,000 words compared with 4.97 for the working-class speakers ($p < .001$). However, the difference was not only in the use of “uncommon adverbs.” The working-class speakers rarely used *very* and *quite*: they used *very* with a frequency of 1.0 per 1,000 words compared with the frequency of 3.49 per 1,000 words for the middle-class speakers ($p < .001$). Similarly, the working-class speakers used *quite* with a frequency of 1.0 per 1,000 words compared with the middle-class speakers’ frequency of 2.49 per 1,000 words ($p < .002$). Both groups of adolescents barely used *very*, but the middle-class adolescents used *quite* more than twice as often ($p < .01$) as the working-class adolescents.

Bernstein (1971, p. 102) found that the middle-class boys used significantly more adjectives than the working-class boys. In Ayr, the middle-class speakers used adjectives twice as frequently (22.41 per 1,000 words) as the working-class speakers (11.74 per 1,000 words), which is statistically significant ($p < .05$). There was a similar pattern in Glasgow with both the adults and the adolescents. The middle-class adults used adjectives with a frequency of 34.16 per 1,000 words compared with 24.74 per 1,000 words for the working-class adults. The middle-class adolescents used adjectives with a frequency of 29.79 per 1,000 words compared with 24.74 per 1,000 words for the working-class adolescents, but in neither case were the differences statistically significant. The middle-class adults, however, used evaluative adjectives (e.g., *brilliant*, *horrendous*, *impeccable*) twice as frequently as the working-class speakers ($p < .004$).

Bernstein (1971, p. 104) found that the middle-class boys used fewer personal pronouns than the working-class boys. This was true of the Glasgow speakers, both adults and adolescents, but the differences were not statistically significant. In both Ayr and Glasgow, the middle-class speakers used significantly more *wh*-forms of relative pronouns (*who*, *which*) than the working-class speakers, both adults and adolescents ($p < .001$).

Macaulay (2005) examined 42 discourse features in the Glasgow conversations and found 46 statistically significant differences, of which only 10 referred to social-class differences, compared with 16 for gender differences, and 20 for age differences. This underlines the danger of taking one subset of the population (e.g., adolescent boys) and generalizing the results to the population as a whole. Bernstein's methodology was totally inadequate (Macaulay, 2005, pp. 43–4) but his insights were remarkably acute, and many of them have been confirmed in the results cited above. It is unfortunate, however, that few researchers followed his example in conducting an empirical study of social-class differences in grammar. If they had, there might have been much more to report in the present entry. It is to be hoped that future researchers into social-class differences in language will pay more attention to syntax. In order to do that, they would be advised to follow the examples of Stuart-Smith (1999) and Docherty and Foulkes (1999) in collecting extended examples of spontaneous conversation.

Grammar and the Influence of Society and Culture

ANNA GLADKOVA

Introduction

The influence of society and culture on grammar is studied within two major approaches. The sociolinguistic approach analyzes grammatical variation (along with any other linguistic variation) in relation to societal variation and cultural norms. Society and culture are treated closely in this approach with a particular focus on a “behaviorist” interpretation of culture (see Sarangi, 2009). The most prominent work in this regard is research done by William Labov and others (e.g., Labov, 1972, 1980, 2006).

An approach that is mainly concerned with the influence of culture on language is ethnosyntax. Here a “mentalist” or “semiotic” interpretation of culture (see Sarangi, 2009) is of more importance. This entry will represent the perspective of the ethnosyntax approach.

The term “ethnosyntax” was coined by Wierzbicka (1979) to introduce a new perspective into grammatical studies with a particular focus on cultural meaning. She defines connections between grammar and meaning as follows:

Every grammatical construction encodes a certain meaning, which can be revealed and rigorously stated, so that the meaning of different constructions can be compared in a precise and illuminating fashion, both within one language and across language boundaries.

Grammar is not semantically arbitrary. On the contrary, grammatical distinctions are motivated (in the synchronic sense) by semantic distinctions; every grammatical construction is a vehicle of a certain semantic structure; and this is its *raison d'être*, and the criterion determining its range of use. (Wierzbicka, 1988, p. 3)

Ethnosyntax is a form of language studies which relies on the view that language and culture are closely connected. The most relevant interpretation of “culture” in this regard has been offered by the anthropologist Clifford Geertz. In his view, the concept of culture denotes “a historically transmitted pattern of meanings embodied in symbols, a system of inherited conceptions expressed in symbolic forms by means of which men communicate, perpetuate, and develop their knowledge about and attitudes towards life” (Geertz, 1973, p. 89). As emphasized by Wierzbicka, a key to decoding cultural meanings embedded in grammatical structures lies in a semantic approach to studying grammar.

Two senses of ethnosyntax can be distinguished—a “narrow” and a “broad” sense (Enfield, 2002; Goddard, 2002). Ethnosyntax in a “narrow” sense aims to locate and articulate cultural understandings that are embedded in the meanings of particular grammatical structures. Ethnosyntax in a broad sense studies how pragmatic and cultural rules affect the use of grammatical structures. Ethnosyntax in this sense is comparable to other studies in the area of pragmatics, such as ethnopr pragmatics (Goddard, 2002, 2006) and ethnography of speaking (e.g., Gumperz & Hymes, 1972).

The following discussion will provide examples of studies in ethnosyntax in its broad and narrow senses. It will also focus on two traditionally distinguished components of grammar—morphology (inflection and word formation) and syntax (a system of rules which describe how all well-formed sentences of a language can be derived from basic elements).

Before proceeding, a methodological remark is due. When it comes to identifying cultural themes in language the metalanguage of description is of paramount importance. Since the goal of a cultural analysis is to identify cultural ideas as they are embedded in language, it is crucial to avoid an ethnocentric bias in the analysis. This can be achieved by the use of a language-neutral methodology known as the natural semantic metalanguage (or NSM; see www.une.edu.au/bcss/linguistics/nsm/). NSM comprises 63 empirically identified universal meanings (along with a limited number of more complex meanings known as semantic molecules), which combine with each other in certain ways to form a mini-language. This metalanguage lies at the core of every language (e.g., Goddard & Wierzbicka, 2002; Goddard, 2008). NSM is applied in semantic studies of words and grammatical constructions to formulate explications, as well as in studies of cultural and pragmatic factors underlying language use to formulate cultural scripts. Several of the examples provided in this entry represent studies which rely on the use of NSM as a methodological tool.

Cultural Ideas Reflected in Morphology and Syntax

Morphology

Diminutives are an interesting example of a linguistic phenomenon encoding cultural meaning at the level of morphology. The term “diminutive” refers to a formation of a word that conveys the idea of “smallness” of the object or quality named, generally in conjunction with an attitude of intimacy or endearment toward it. This phenomenon is found in many languages, but its scope and exact semantic content vary from language to language. Here this variation will be demonstrated using Russian, Colombian Spanish, and Australian English.

Russian has a highly developed system of expressive derivation. It applies to nouns, adjectives, and adverbs (e.g., *nos* ‘nose.NOUN.MASC.SG’ > *nosik* ‘nose.DIM’; *solnce* ‘sun.NOUN.NEUT.SG’ > *solnyško* ‘sun.DIM’; *krasivyj* ‘beautiful.ADJ.MASC.SG’ > *krasiven’kij* ‘beautiful.DIM’; *bystro* ‘quickly.ADV’ > *bystren’ko* ‘quickly.DIM’). The system of expressive derivation in personal names is also extremely rich and is largely consistent with the one for nouns. For example, a feminine name *Ljudmila* has the following derivatives (among others): *Ljuda*, *Ljudočka*, *Ljudka*, *Ljudok*, *Ljudusik*, *Ljudasik*, *Ljudaša*, *Ljusja*, *Ljus’ka*, *Ljusik*, *Ljusenok*, *Mila*, *Miločka*. A masculine name *Jurij* has the derivatives *Jura*, *Juročka*, *Jurik*, *Juron’ka*, *Juranja*, *Juraša*, *Jurčik*, *Jurasja* (among others). A list of comparable length can be produced for almost any Russian personal name. Each form conveys a different meaning, and the choice of the form depends on the attitude the speaker wants to express toward the addressee. The nuances of these meanings, however, are difficult for cultural outsiders and learners of a language to grasp (see Gladkova, 2007). There is a strong association between diminutives and small children (as diminutives are used to talk about and to children), but they are also used among adults in colloquial speech.

Wierzbicka (1992) argues that with a meaning-based approach to grammar one can unravel cultural information embedded in the derivative forms of personal names and communicate it successfully to language learners. She proposes semantic formulas as representations of meanings of models of expressive derivation. We will illustrate her studies on the basis of two forms only. The most common forms with the suffix *-očka* (*Juročka*, *Ljubočka*) suggest a particularly small size and good feelings associated with

small children, not simply children as such. The invariant of meaning of this form can be represented in universal human concepts as they are identified in NSM as follows (see Wierzbicka, 1992, p. 247):

- (1) *Ljudočka, Juročka*
 - (a) I feel something good towards you
 - (b) like people feel when they say things to small children

The suffix *-ik* has boyish associations, in both masculine and feminine forms. Thus the invariants of meaning are as follows (see Wierzbicka, 1992, p. 251):

- (2) *Jurik, Marik* (masculine names)
 - (a) I feel something good towards you
 - (b) like people feel towards small boys
- (3) *Ljusik, Svetik* (feminine forms)
 - (a) I feel something good towards you
 - (b) I feel something good when I say things to you
 - (c) I want to say things to you as if you were a small boy, not a small girl

Formulas of this kind allow us to show overlapping components of meaning in the structures under investigation as well as their differences. Explications (1), (2), and (3) have identical components (a). Their differences lie in the fact that explication (1) has reference to "small children," while explications (2) and (3) have reference to "small boys" with (3) also containing reference to "small girls."

Reference to small children has not been shown to apply to all forms of expressive derivation in Russian as it is not relevant in the forms with the suffix *-en'ka* (e.g., *Katen'ka*, *Miten'ka*) and with the suffix *-uška* (e.g., *Nikituška*, *Annuška*) (Wierzbicka, 1992). This fact suggests that a reference to children cannot be claimed to be an invariant of meaning for all forms of diminutives in Russian.

Linguistic elaboration in the domain of expressive derivation in Russian has a significant cultural importance. In particular, this elaboration can be related to two important cultural themes of Russian. First, it is reflective of a general cultural value placed on an open and spontaneous display of emotions. Second, it relates to the value of displaying affectionate feelings in intimate personal relations. These cultural rules can be formulated in the form of cultural scripts as follows (see Wierzbicka, 1999):

- (4) [many people think like this at many times:]
it is good if other people can know what someone feels
- (5) [many people think like this at many times:]
if I know someone well
when I feel something good towards this someone
it is good if this someone can know it
when I say something to this someone
- (6) [many people think like this at many times:]
if I know someone well
when I say something to this someone
it is good if this someone can know what I feel towards this someone
when I think about this someone

Spanish, like Russian, is also rich in expressive derivation. However, there is no complete overlap between the two systems. Travis (2004) employs Wierzbicka's approach in analyzing a diminutive suffix *-ito/-ita* in Columbian Spanish. She identifies its several uses on the basis of a corpus study and demonstrates that this suffix serves several functions—from its core uses in relation to children to expressing affection, contempt, and hedging speech acts. Travis argues that the use of diminutives in Colombian Spanish is based on the prototype of using a diminutive when speaking to children and, therefore, implies feelings of the kind that can be felt when speaking to children. This prototype can be formulated in the form of a cultural script as follows (see Travis, 2004, p. 261):

- (7) [many people think like this at many times when they say something about someone:]
 when I say this about this someone, I feel something good towards this someone
 like people can feel towards a child when they are saying something to this child

Travis notes that semantic and pragmatic functions of a diminutive in Spanish differ from the ones in Russian in that a Spanish prototype of a diminutive is child-focused, while in Russian it is not.

Australian English has a distinctive diminutive form, such as *Chrissy prezies* (Christmas presents), *barbie* (barbecue), *salties* (salt-water crocodiles), *freshies* (fresh-water crocodiles), *Brissie* (Brisbane), *Tassie* (Tasmania). Goddard and Wierzbicka (2008) argue that the use of this “diminutive” is different from the use of a “regular” diminutive (e.g., *birdie*, *horsie*) in that it involves abbreviation and it does not convey a “childish effect.” The Australian forms reflect a “familiarity” effect (they apply to objects or phenomena very familiar to people in Australia) and the “unimpressed” or “undaunted” attitude that “it is not a big thing” (as a shortened form of the word indicates). Goddard and Wierzbicka (2008) propose the following explication for these forms:

- (8) *barbie*, *freshies*
 (a) something
 (b) when I say this about it, I think about it like this:
 (c) “it is not something big
 (d) when I say something about it, I don't want to say it with a big word
 (e) people here don't have to think much about things like this
 (f) because they know things like this well”
 (g) when I think about it like this, I feel something good

This explication demonstrates differences in meaning between the Australian forms and Russian and Spanish forms. It also shows differences in underlying cultural values; rules of “emotion expression” in Russian (scripts (4)–(6)) are not applicable to the Australian context where the expression of emotions is toned down.

Thus, with the help of a refined methodology of semantic analysis it can be demonstrated that “diminutive” forms in Russian, Columbian Spanish, and Australian English convey cultural attitudes and that these attitudes differ across these languages. Other well-researched examples of culturally salient morphology are honorifics in Japanese (e.g., Loveday, 1986; Prideaux, 1970), Korean honorifics and cultural scripts (Yoon, 2004), case in Polish (Wierzbicka, 2008), and reciprocal constructions (Nedjalkov, 2007; Wierzbicka, 2009).

Syntax

As an illustration of how cultural meaning can be conveyed at the level of syntax, we will consider a link between constructions with the verb *let* in English and cultural ideas of “personal autonomy” and “nonimposition” on the basis of Wierzbicka's (2002) study.

The existence of a large number of constructions with the verbs *make*, *have*, and *let* in English allows Wierzbicka (1988, 1998, 2002) to argue for the cultural salience of the domain of causal relations in modern English. She shows that for each verb it is possible to distinguish several semantic invariants of constructions, all characterized by a slight difference in meaning. On the basis of a detailed semantic analysis she proposes the following classification of constructions with the verb *let* and formulates a semantic prototype for each of the constructions:

- Let* of "permission" (*She let him go to the party*)
- Let* of "non-interruption" (*She let him sleep*)
- Let* of "apparent indifference" (*She let him cry*)
- Let* of "non-prevention" (*She let him fall*)
- Let* of "tolerance" (*Let her be!*)
- Let* of "shared information" (*Let me know what happened*)
- Let* of "offering to perform a service" (*Let me open the door for you*)
- Let* of "suggestion" (*Let's do Z!*)
- Let* of "cooperative dialogue" (*Let me conclude by saying . . .*)
- Let* of "cooperative interaction" (*Let me talk to him*)
- Let* of "cooperative thinking" (*Let me think . . .*)

Wierzbicka compares the English constructions with similar constructions in German and Russian, showing that these languages have less semantically diverse causative constructions and that some of the English constructions do not have idiomatic equivalents in either German or Russian.

Wierzbicka puts forward a hypothesis explaining cultural roots of this elaboration in English:

as democracy developed in a large-scale modern society—first of all, in America . . . —a new style of human relations evolved, to accommodate the need for both an increased scale of interpersonal interactions and a new footing on which these interactions were to be conducted . . . The new managerial type of society, too, needed an increased scale of interpersonal causations: for the society to function smoothly and efficiently, lots of people had to be, roughly speaking, told what they were to do. This had to happen, however, in the context of a democracy, where people might be willing to take "directions" or to follow "instructions" but not to obey "orders" or "commands." (Wierzbicka, 2002, p. 166)

Other interesting examples of studies exploring cultural attitudes embedded in syntactic structures are Wierzbicka (1992) and Goddard (2002) on dative constructions in Russian (e.g., *Mne ne spitsja* 'I.DAT no sleep.REF') and the cultural themes of "fate" and "passivity."

Grammatical Structures and Cultural Influence on Their Use

In this section we provide an illustration of variation in the use of grammatical structures due to the influence of cultural factors. As a case study we will consider Eades' (1982) research on information-seeking techniques in Australian Aboriginal English in Southeast Queensland. The author shares her personal experience of collecting linguistic data in the area and reports difficulties she faced in trying to elicit information from Aboriginal people. She notes that commonly Aboriginal people are "confused, dysfluent or noncompliant when questioned by means of an interrogative sentence like *Were you very young?*, the most usual type of question for MCWA [Middle-Class White Australian] people" (Eades, 1982, p. 65).

Eades identifies several linguistic models of information-sharing techniques in Aboriginal English, among them using a declarative clause with question intonation, “triggering,” and the use of interjections and repetitions. She explains “triggering” as

a technique consisting of devices, often followed by silence, intended to lead the knowledgeable person to impart information. In the most common triggering strategy the person desiring substantial information makes a relevant statement, presenting something he already knows about the topic. This is followed often by silence and then by the knowledgeable person talking on that topic, if he desires. (Eades, 1982, p. 76)

Interjections and repetitions (e.g., *yeah*, *mm*, *oh*, *what?*, and the like) are also commonly used to encourage the speaker to give further information. Eades notes that direct questions are also used to elicit information, but less frequently than other strategies.

Eades explains the specificity of this practice, as compared to Anglo-English, by a prevailing different system of personal relationships, as well as a different cultural attitude to information and knowledge in Australian Aboriginal societies. Socialization among Aboriginal people is strictly regulated by their kin relationships. Eades comments:

Traditional Aboriginal society . . . was and is based on small-scale groups. Each person has a particular kin relationship with every other person with whom he comes into contact—if not a blood relationship, then by extension, a classificatory kinship relationship. These kin relationships play a crucial part in all interaction. . . . Clearly, then, the great need to compel interaction between people in MCWA society doesn’t exist in traditional Aboriginal society. (Eades, 1982, p. 67)

Regarding cultural rules governing sharing information and knowledge she writes the following:

In Aboriginal society . . . knowledge is not free and easily-acquired good. Knowledge is acquired or passed on as a part of social interaction and is subject to strong controls in many instances. For example, much knowledge of religious and ritual matters is strictly controlled so that only initiated men may know certain songs, stories and places. (Eades, 1982, p. 69)

Concluding Remarks

Language is highly sensitive to cultural and societal processes. Grammatically elaborated areas of a language commonly embed meanings or ideas that are particularly salient in the collective psyche of a people. Knowledge of these meanings or ideas can equip cultural outsiders with more effective and successful tools of communication with the representatives of the culture.

This entry has provided some examples of studies illustrating cultural significance of grammar within the approach of ethnosyntax. These investigations are of particular importance to applied linguistics in general and language teaching in particular. The proposed formulas can be applied in language teaching to explain meanings and use of grammatical constructions. The use of universal human concepts makes it possible to translate these formulas into any language without any change in meaning.

Grammar and the Research Article

LYNNE FLOWERDEW

Introduction

The research article (RA) is one of the most important genres in academic discourse, one reason being that progression in an academic career can hinge on the quality and quantity of an academic's publication record. Style manuals on how to write and publish a research article tend to be rather prescriptive with regard to tense usage, invariably give advice encouraging the use of an objective and impersonal style characterized by grammatical constructions such as the passive and nominalizations, and sometimes advocate the avoidance of personal pronouns *I* and *we*. But to what extent does this advice hold true when measured against analysis of authentic RAs?

Theoretical Framework

An optimum starting point for an overview of the RA is Swales's chapter 7 in his 1990 seminal volume on genre analysis and his follow-up work revisiting the RA in his 2004 publication on research genres, as most studies approach analysis of RAs from this theoretical perspective. Broadly speaking, genres are a social construct which shape and are shaped by the ways we interact, thus underscoring the importance of role relationships among writer and reader(s) (Berkenkotter & Huckin, 1995). The role of grammar in the RA has mainly been investigated within a paradigm of the *structural* and *rhetorical* conventions of this genre. *Structural* refers to the classic IMRD organization—that is, Introduction, Methods, Results, and Discussion sections of experimental research articles—although as noted by Swales (2004, p. 208), this standard pattern would not be applicable in the case of theoretical RAs as found in the disciplines of theoretical physics, mathematics, and some areas in economics, which employ a logico-argumentative model. *Rhetorical* conventions relate to the communicative purpose of the RA overall (RAs are uncontestedly viewed as persuasive artifacts), or to the communicative purpose of individual sections or “moves” within different sections. For Swales “A ‘move’ in genre analysis is a discoursal or rhetorical unit that performs a coherent communicative function in written or spoken discourse” (2004, p. 228). For example, prototypical moves in RA Introductions, the most widely researched section, would include “establishing a territory,” “establishing a niche,” and “occupying the niche,” commonly referred to as the CARS (create-a-research-space) model. In the 1980s most genre-based research on the RA centered on analysis of small samples of one or two texts, whereas later studies make use of computerized corpora of RAs.

It is against this backdrop of the structural and rhetorical conventions revealed through genre analysis, also taking into account disciplinary differences among hard and soft knowledge domains (sciences/engineering vs. humanities/social sciences), that the “grammar” of the RA is mainly reviewed. The focus is thus on how and why certain grammatical devices constituting the “technical grammar” of English (see Halliday & Martin, 1993) are deployed to perform different rhetorical functions in addressing both peers and the wider academic community.

Tense Usage

Style guides for writing the RA can be somewhat prescriptive, reducing tense usage to the set of following “rules”:

- Use the present tense for stating previously published findings which have become accepted scientific knowledge or are a universal truth.
- Use the past tense for the description of methods and results in the current study.
- Use the past tense for attribution of sources (e.g., *Smith reported that . . .*).

Let us now see how these rules hold up in light of findings on tense usage, a grammatical category which was the focus of much of the early research on RAs. While the second piece of advice is borne out by research findings (see, e.g., Nwogu’s 1997 genre-based research on a corpus of 30 medical research papers), the other two are somewhat incomplete.

While it is true that the present tense is used for stating findings which have become accepted scientific knowledge, such as “Streptomycin inhibits the growth of *M tuberculosis*” (Day & Gastel, 2006, p. 192), this statement presents only half the picture. Researcher-writers report or state previously published findings for a variety of communicative purposes. Lackstrom, Selinker, and Trimble’s (1973, p. 133) research, one of the first studies to align tense choice with rhetorical purpose, shows that *past research* is presented in both the past and present perfect tenses. When the past research does not bear directly “in terms of importance-on the work” described in the report, the past tense is used. In contrast, when the past research is directly related “in terms of importance-to the work” described, the present perfect tense is used.

Lackstrom et al.’s (1973) observation that the use of the present perfect signals “importance-to the work described” can be seen in terms of Swales’s moves in RA Introductions. In the opening “establishing a territory” move, the present perfect is used for claiming centrality and making topic generalizations. An example from Oster (1981, p. 78), taken from the introduction to a chemical engineering report, reads as follows: “Sustained isothermal, concentration oscillations *have been observed* in recent experimental studies involving the oxidation of either CO or H₂ over metal catalysts [1–9]. Various mechanisms *have been suggested* to explain this interesting phenomenon.” The present perfect can also be found in the second move of the Introduction, “establishing a niche,” with some form of negative marker to counterclaim or indicate a gap in the field, such as “In contrast to the large number of investigations of wall-to-wall head transfer in gas-fluidized beds, comparatively little [2–7] *has been published* on heat transfer in liquid-fluidized beds” (Oster, 1981, p. 78), serving to mark a shift to the writer’s own work (Myers, 1992), that is, “occupying the niche.” Nwogu (1997) reaches a similar conclusion in his genre analysis of medical RAs when he states that in reviewing related research in the Introduction the present perfect is used for research whose results have implications for new research, a use listed in general reference grammars.

The above examples from Oster are both nonintegral citations, that is, where reference to the author is given in parenthesis or by footnote numbers. Integral citations are those where the name of the cited author occurs in the citing sentence, usually as subject, and are far more common in the soft sciences (Hyland, 1999). While, as stated previously, style guides recommend using the past tense for integral citations with the author in subject position, as in *Smith reported that . . .*, research findings show the situation to be far more complex than is reflected in this bald statement, as the past, present perfect, and present tenses are all possible. Swales (1990, p. 154) suggests that the choice of tense depends on how far the writer wishes to distance themselves from the reported findings, with the present tense used to pave the way for a critical discussion.

As for the presence of verbs in the continuous or progressive forms, Swales (1990, p. 137) points out that these forms “occur very rarely, if at all, in *any* section of an RA.” While this observation is valid for RAs in the science and engineering fields, Hyland’s (1998, p. 120) corpus-based research across a variety of disciplines shows that philosophers and sociologists occasionally use the progressive aspect to present their work: “*In this way I am confronting fundamental issues of critical social science practice (Soc[iology]).*” Hyland states that this type of dialogic narrative exposition allows the writer to project themselves into the text and express their authorial stance.

Nominalization

The writers of style guides and applied linguists agree that one of the functions of nominalization in science writing is to create an aura of impersonal objectivity, similar to the use of passive verbs. Compare the two sentences below from Halliday (1993, pp. 61–2):

We used an ISOL and thus could experiment even where it was difficult.

The experimental difficulties were resolved by the use of an ISOL.

What is often omitted from mention in style guides, though, is that nominalizations allow the writer to pack a lot of information into the noun phrase (NP), which, like passives, can make the meaning less explicit. Martinez (2001, p. 233) gives the following example of nominalizations from a biology RA: “Incubation of washed normal human platelets . . . results in significant increase in platelet-bound antibodies.” If the verb *incubate* were used instead of its nominal form *incubation*, the underlying concept would have to be expressed across two sentences instead of compressed into one; for example, *Normal human platelets were washed and left to incubate. This resulted in . . .* Dubois (1982, cited in Swales, 1990) has noted the effect of “stacking” in noun phrases that takes place across sentences and clauses; for example, in the NP *the heavy beef heart mitochondria*, *mitochondria* is used as a premodifier when it is referred to later in the RA, *well coupled mitochondrial particles*. Biber and Gray’s (2010) three-million-word corpus-based study of RAs provides further support that writing in the RA is structurally “compressed,” involving complex nominalizations. The sentence “these stages are marked by the appearance of new systemic mechanisms and corresponding levels of complexity” (p. 6), while simple in terms of syntactic structure, with only one main verb, contains multiple prepositional phrases embedded within the NP. As Biber and Gray point out, this belies the common belief that academic writing is structurally elaborate through relative clause use in which meaning relations are expressed explicitly.

Passive Versus Active Voice

Some style guides recommend using the passive voice to maintain impersonalization, while others specify the use of either solely *I/we* or the passive. Is this advice contradictory? Moreover, if there is a choice between active and passive, what determines this choice?

Sometimes, it is the information structure of the sentence which determines whether the active or passive is used. According to Halliday’s (1978) given–new paradigm and his principle of end-weight, information new for the reader, and also long and complex elements, tend to be placed toward the end of the sentence (see Biber, Johansson, Conrad, & Finegan, 1999, for more details). Such is typically the case with equations. In the sentence “The radiative transport is described by the aediative diffusion equation,” the equation

described is quite long (and may also be new information for the reader). As new information usually carries a high information load, the two typically converge, as in the following: “Equating the two temperatures, for example, yields . . .” (Tarone, Dwyer, Gillette, & Icke, 1988, p. 201). However, the given–new information paradigm does not seem to operate in Methods sections of RAs, where new information is often placed in subject position, giving the impression “that Methods sections often read like checklists” (Swales, 1990, p. 168).

Methods sections in *experimental* RAs tend to be dominated by impersonal passive constructions, as commonly noted in style guides and also confirmed by corpus findings (Martínez, 2001). However, as *theoretical* RAs do not have clearly discernible Methods sections but rather consist of a series of arguments to build a case for a specific phenomenon (Swales, 1990), they employ more active verbs overall. Passive verbs in the Methods section in RAs are usually agentless, placing focus on the objects under investigation and thus used as a distancing strategy by the writer-researcher, as in “The subjects were tested individually in a quiet room at their school” (Martínez, 2001, p. 237). It is important to note, though, that the active voice can also signal impersonality when used with an inanimate subject. Consider the following two examples from Rundblad’s (2008, p. 25) analysis of Methods sections based on nine medical research articles:

- (1) interviews *were carried out* by researchers blind to the duration or sequence of blocks. (BMJ 2001).
- (2) *This well validated semistructured interview* uses investigator based criteria to assess the frequency and severity of antisocial behaviours (BMJ 2001).

Rundblad points out that in both sentences the research method (i.e., the interview) rather than the researchers is the object of study. A metonym (*interview* in example 2), a rhetorical strategy used to describe something indirectly, serves to obscure and anonymize the researchers (using a possessive adjective would render the information less impersonal, as in *Our semi-structured interview uses . . .*). However, when an active form occurs with the subject *we*, this combination brings the writer’s voice into the text, as in *In our semi-structured interview, we used . . .* More information is given on the use of personal pronouns below.

Personal Pronouns

In addition to the use of a personal pronoun to introduce or discuss research methodologies, other purposes identified by Hyland (1998, pp. 118–19) are to organize arguments and structure texts, as in *In this paragraph we report a comparison between . . .*, and to explicitly indicate the writer’s stance toward findings or to align themselves with a theoretical position, as in *I argue for* or *we concur with*. This exclusive use of *I* and *we*, to refer solely to the writer and other people associated with the writing, is also conceived as a form of self-promotion (Kuo, 1999; Harwood, 2005). The use of the inclusive pronoun *we* referring to the writer and reader together is mainly confined to RAs in philosophy to engage readers rhetorically in the text, as in “we cannot expect this paradox to . . .” (Hyland, 1998, p. 113). Imperatives and phrases such as *let us consider*, found to occur across all disciplines, are other devices whereby writers seek to involve the participation of the reader (Swales et al., 1998; Hyland, 2002). Thus, contrary to the advice given in some style guides to maintain an objective, impersonal style, the pronoun system is exploited by writers of RAs for maintaining the writer–reader relationship and allowing the writer an authorial voice.

Stance Markers

The way that writers position themselves toward the propositional content of the RA is realized through a variety of stance markers. Four types of stance markers, namely self-mentions, attitude markers, boosters, and hedges, are listed in Hyland's (2005, pp. 178–82) taxonomy, based on his corpus analysis of 240 RAs from eight disciplines. Self-mention covers the pronoun system outlined above. Attitude markers indicate the writer's attitude toward the propositions, conveying surprise, agreement, importance, and so forth. Sentence adverbs, such as *unfortunately*, and adjectives, such as *logical*, *remarkable*, are used to explicitly signal writer attitude (attitude is indicated less explicitly through the use of subordination and comparatives). Boosters, adverbs modifying verbs, as in *we obviously do not see*, and adjectives, as in *this seems highly dubious*, help writers to present their work in an assured, confident style. However, while claiming significance and contribution to the field for their work, at the same time writers also use a variety of hedging devices to present information as an opinion rather than fact, for a variety of reasons: as a politeness strategy and to save face (Myers, 1989), and to conform to the rhetorical conventions of the discourse community to forestall anticipated criticism to the work presented (Hyland, 1996). Hedges are typically realized by modal verbs expressing possibility (*may*, *might*), semi-auxiliaries (*seem*, *appear*), compound hedges (*it may suggest*), adverbs (*probably*), and approximators (*somewhat*, *occasionally*) (Salager-Meyer, 1994).

Conclusion

Grammar and the RA have been discussed from a discourse-based rhetorical perspective within a genre-based framework. While advice in style guides on the use of nominalizations, the passive, and tense usage is generally sound, findings from applied linguistic research point to a much more nuanced and complicated picture of how the “technical grammar” of English operates in RAs.

Grammar Teaching and the Workplace

LYNDA YATES

Introduction

Recent reviews of workplace language use and education make frequent reference to skills, competencies, or literacy, and grammar per se scarcely rates a mention (see, for example, Roberts, 2005, 2010; Duff, 2008; Newton & Kusmierczyk, 2011). More concerning, perhaps, is the invisibility of grammar in many workplace-related needs analyses (see, for example, Cowling, 2007). There are several causes for this tendency to focus on communicative skills and downplay the role of grammar in workplace settings. The history and geography of second language acquisition (SLA) research have influenced attitudes to grammar teaching, as have the perceptions that sentence-level descriptions have their limitations in explaining authentic communication. Popular misconceptions of what it is to learn and use a language, aided and abetted, no doubt, by lingering childhood memories of stultifying teacher-fronted grammar lessons in school, have also played a role.

While it is certainly appropriate for workplace language training to have a major focus on developing communication skills relevant to task, audience, and context, if learners are to extend and develop these skills creatively so that they can respond to new demands and new contexts, then they will also need to understand the role of grammar in making and understanding meaning. Moreover, adult learners themselves place a high value on learning grammar, and see appropriate lexicogrammatical control as an important part of achieving their language and communication goals (Rodríguez, 2009). The issue, therefore, is not one of whether grammar has a place in language programs for and in the workplace, but how it can be integrated in a sociolinguistically sensitive way that best highlights for learners the crucial role it plays in successful spoken and written communication at work.

The focus of this entry is to explore some of the ways in which grammar is relevant to the teaching and learning of language, particularly English, in and for the workplace. I will first briefly discuss some of the influences on the teaching of grammar in English-language teaching (ELT) generally before considering the contribution of developments in discourse and functional grammars, genre, language for specific purposes (LSP), and recent research in workplace interaction to workplace language education.

Attitudes to SLA, Grammar, and Language Teaching

As in other sectors, workplace language teaching methodology and curriculum have been influenced by debates in SLA. The work of Krashen and colleagues in the 1970s and 1980s fostered strong forms of communicative language teaching that eschewed an overt focus on form in the classroom, particularly in North America. However, following research in Canada and elsewhere suggesting that some explicit attention to form might be necessary, or at least useful (see discussion in Rodríguez, 2009), there has been a renewed interest in focusing on form in language teaching, including in workplace contexts (Dyson, 2002; Lewandowski, 2007).

Similarly, trends in the teaching of writing have impacted on attitudes to the role of direct attention to grammar. In the 1980s, process approaches to writing sought to move

DOI: 10.1002/9781405198431.wbeal0474

away from the direct teacher-fronted instruction and overly mechanistic attention to grammar found in some classes by emphasizing the role of the individual creative writing process supported by language conferences (Raimes, 1983). Such approaches downplayed the role of overt grammatical instruction in a bid to allow writers to find their own individual voice and express their own meanings (but see Hegelheimer & Fisher, 2006, for a more recent, corpus-informed approach to providing a grammatical reference resource to supplement process approaches). This focus on the individual voice, however, found its critics in those concerned that not all developing writers had the same wealth of literary experiences on which they could draw. There was growing interest, therefore, in the value of guiding students through the analysis of model texts which involved explicit attention to generic structure and grammatical construction. Genre approaches offered the potential to focus on both context-relevant texts and the underlying systems of meaning that gave rise to them. In some areas, therefore, an overt focus on lexicogrammar underpinned by genre analysis and functional grammar gained in momentum, and was adopted not only in schools but also on workplace programs for adult immigrant learners particularly in Australia (Joyce & Burns, 1992).

Language in the Workplace and Workplace Programs

The recent period of rapid industrial change has increased the demand for language skills in the workplace. Globalization and mass migration have meant that English is increasingly used as a lingua franca in multinational corporations and multicultural workplaces. Of course, workplaces vary enormously not only in size and character, but also in their workforce, and consequently in their practical and sociolinguistic concerns. Language programs designed to prepare adults for the workplace—and sometimes conducted in the workplace—are therefore similarly diverse, and range from white-collar professional and graduate-level programs, offering managers and technical experts the opportunity to fine-tune their language proficiency, to classes addressing the on-the-job demands on factory-floor operatives or preparing newly arrived immigrants to find a job.

For those working in what Roberts (2010) refers to as “the wrong kind of multilingualism” (p. 221), that is, blue-collar workers in low-level multicultural industrial environments, restructured ways of working have required higher levels of proficiency in both spoken language and literacy. The sophisticated interaction required by teamwork and newly implemented quality assurance systems, for example, can marginalize those less proficient in English, while the increased requirement for the documentation of various functions and processes that were previously only reported orally places greater demand on literacy skills (Mawer, 1992; Hunter, Belfiore, Defoe, Folinsbee, & Jackson, 2008).

How language is actually used in the workplace has been researched from a range of perspectives, including language socialization and ethnographies, corpus linguistics, various kinds of discourse analysis and speech acts, and conversation analysis (see discussion in Duff, 2008; Newton & Kusmierczyk, 2011). While in such studies spoken language has often been the focus of attention, studies of workplace or technical language for overtly pedagogical purposes, that is, for language for specific purposes (LSP) or English for academic purposes (EAP), have often focused on written communication.

The issue of how workplace language education should be approached and what it should cover is a contentious area. There is tension between perspectives which view workplace programs unproblematically as offering low-level immigrant workers the opportunity to improve their English and thus a pathway to social and economic advancement, and a concern that by focusing on workplace-relevant basic instruction, programs may simply reinforce and reproduce the inequities of the system (Warriner, 2010; and see discussion

in Roberts, 2005). However, an effective program would surely both seek to extend learners' proficiency in ways that address current workplace needs and seek to build the foundation for their language needs into the future. In order to build this foundation, it is vital for learners to do more than gain control of formulaic language: they also need to develop an understanding of the systematic ways in which grammar is used to construct meaning through extended interactions and texts.

In line with strategic concerns to be industry-relevant, however, national goals, guiding principles, and curriculum frameworks for immigrants tend to be framed in terms of communicative objectives and skills, as in, for example, the Canadian Benchmarks and the Certificates of Spoken and Written English in Australia. Such frameworks can, however, as we shall see below, combine very successfully with a focus on functional grammar. Thus even curricula and objectives which are not expressed in overtly grammatical terms can nevertheless allow a focus on how structure contributes to meaning in context. In this way they can provide the basis for syllabus and teaching approaches that will enable learners to develop a control of English that is not limited to their current jobs but transferable to different workplaces and situations.

Genres and the Workplace

Genre approaches are compatible with competency-based curriculum frameworks and the pragmatic needs of the workplace in that they offer a way of analyzing and teaching language that focuses on how texts are structured and realized in context to express meaning. Cheng (2008) identifies three broad strands that have been influential: the new rhetoric approach to written composition; the genre approaches based on systemic functional grammar taken in Australian school and adult contexts; and English for specific purposes (ESP) approaches to written text. The latter two are particularly applicable in workplace contexts.

The text-focused teaching approaches taken in Australia and elsewhere draw on systemic functional grammar (Halliday, 1985) and genre theory. These fostered a close attention to both the purposes of a text and the lexicogrammatical choices made by the speaker or writer to achieve their communicative goal. Language use is seen as goal directed, purposeful, and related to both the wider cultural context and the specific influential context of the situation. The former gives rise to socially crafted ways of achieving a particular purpose or genres that have identifiable stages in which different lexicogrammatical patterns are characteristic. These patterns are the result of deliberate and systematic choices that reflect the specific context of situation in which they are produced (for further detail see, for example, Coffin, 2003). It is this close connection between the structure of texts and how and why they are realized that makes genre approaches so appropriate for adult language learning in workplace-relevant contexts.

In Australia in the 1990s, genre analysis work on language across the curriculum in schools was extended to adult and workplace contexts. The national Adult Migrant English Program (AMEP) adopted a competency-based centralized curriculum in line with changes to the national vocational curriculum framework, and a genre approach offered a useful way of highlighting structural and grammatical features of sample texts. It provided learners with insight into the social purposes behind texts used across a range of workplaces and thus a way of understanding the social contexts in which they were embedded. Guided through learning and teaching cycles to produce similar texts, they were able to focus on language and literacy in integrated programs which combined both skills development and a grammatical focus (Joyce & Burns, 1992).

Used to learner-centered curricula, some teachers were wary of the kind of text-focused teaching-learning cycles encouraged by genre approaches and the unfamiliar grammatical

terminology that mastering them entailed. Others, however, found that approaching grammar through text with the explanatory power of functional grammar helped them to highlight for learners—and understand for themselves—why texts took the particular form that they did. One teacher, for example, describes how participation in an action research project on the use of genre with workplace learners revolutionized the way in which she taught grammar and allowed her to move from a somewhat hit-and-miss approach, based on what students had requested and a vague notion of what learners needed, to an approach which enabled her to select the grammatical focus for classes in a more principled way. This involved choosing texts that were relevant for learners and exploiting them in ways that helped to build up grammatical understandings appropriate to their level of proficiency (Lukin, 1995).

As noted above, the LSP goals for white-collar workers and professionals, like those of others in the workplace, have frequently been seen in terms of the spoken and written skills required in business contexts, rather than knowledge of or expertise in grammar. This has favored a focus on spoken skills such as giving presentations and negotiating, or report writing, or the particular demands of a profession or background discipline rather than an explicit focus on the role of grammar (Skulstad, 1999). As in other areas of workplace communication, the need to develop skills, especially spoken skills, is a recurrent theme in feedback from students and workers seeking to improve their workplace language. Yet effective communication in the professions, as elsewhere, relies on being able to express meaning in ways appropriate to the relevant community. It therefore demands not only the ability to reproduce a series of forms appropriately in context, but also the ability to manipulate the lexicogrammatical system that underlies them (Skulstad, 1999; Forey, 2004).

Essential to this kind of creative mastery is also a deep understanding of how and why lexicogrammatical choices are made. A large body of work in LSP, especially ESP, has therefore also drawn on systemic functional grammar as a way of exploring specialized genres and discourses, explaining the relationship between author, audience, and background discipline, and informing language preparation programs for the professional workforce. This drive to provide richer and more explanatory accounts of the structural and lexicogrammatical features of professional and specialized texts, and also to give greater insight into their professional and disciplinary underpinnings, has fuelled a movement away from a reliance on sentence-level linguistics and surface-level grammar and to the use of functional and discourse grammars (Bhatia, 2002).

Discourse and Spoken Grammar

Of great potential interest to those interested in the role of grammar in workplace language education are insights from discourse approaches to grammar. Over the past couple of decades, advances in technology have allowed the examination of large corpora of data, and this has facilitated investigation into how lexicogrammar is actually used over longer spoken and written texts, and how it is used differently across contexts. This ability to analyze longer stretches of language has led to new understandings of how Standard English works and has also helped to illuminate points of grammatical usage that were otherwise difficult to explain to learners. Thus features that are easily explained through reference to sentence-level structure, such as subject–verb concord, determiner–noun agreement, and so on, can be distinguished from those that are discourse-sensitive, such as tense, aspect, and modality, and that are best described in terms of speaker or writer meaning in context over extended texts. Thus grammar should be seen as interacting with discourse and text structure (Celce-Murcia, 1990).

Discourse approaches have also highlighted the differences between spoken and written English (Hughes & McCarthy, 1998; Carter & McCarthy, 2006; Rühlemann, 2008) and thus

potentially liberated ELT, including workplace language education, to see that grammatical accuracy and spoken fluency are not incompatible. Helping adult learners to realize that the grammatical constraints of spoken language are not necessarily the same as those expected in written text is by no means trivial. This insight would have helped me 30 years ago as I struggled to answer the distraught adult learner who asked me very seriously why he was studying grammar when native speakers did not seem to use it! Thus features of spoken grammar can take their place alongside other descriptions of language use to flesh out what it means to use a language in context.

Since the goals for learners of language for the workplace vary around the world, however, it is relevant to consider the issue of how far naturally occurring native-speaker (NS) English is an appropriate goal for everyone. Those communicating with NSs of different varieties will have a vested interest in understanding and perhaps also controlling features of that NS variety, and discourse and spoken grammars are able to provide crucial insight into these and how they fit together in actual communication. Others working in environments where English is a lingua franca (ELF) may, of course, target different goals. For both, however, the ability to access models and explanations derived from long stretches of text will be an advantage. Yet it seems that the old habits die hard, and the full impact of these changes in the way we approach grammar teaching has yet to be fully felt in ELT generally (see Conrad, 2000; Timmis, 2005; Mumford, 2009), and in workplace programs.

One very valuable source of insight into how language is actually used in the workplace and thus how effective communication is achieved there is the output from the Language in the Workplace Project (LWP) (www.victoria.ac.nz/lals/lwp). In a series of studies of naturally occurring language data collected in a variety of New Zealand workplaces, the LWP team has been able to illustrate how people at work project, negotiate, and manage their identities on a day-to-day basis.

Although the analytical focus of much of their work has been sociolinguistic rather than overtly grammatical (for example, Riddiford & Joe, 2010), there are also clear implications for targeted grammatical instruction. In addition to providing relevant models for immigrants seeking to improve their workplace readiness, such studies provide careful analyses of how grammatical forms are actually used to achieve particular communicative goals in the workplace. These authentic descriptions can usefully complement studies which have used elicited data to investigate similar issues. Thus, for example, informative descriptions of authentic requesting behavior in an office (Vine, 2004) corroborate insights from work-relevant role-play studies (Yates, 2010) and can be used for focused instruction (Riddiford & Joe, 2010). In their different ways, these studies highlight how important it is for newcomers to be able to accurately manipulate grammatical form in order to be socio-pragmatically effective in the workplace. As in the discourse and functional approaches to workplace language discussed above, it is the attention to how form functions in context to make meaning that matters, rather than the form itself.

Conclusion

While many workplace-oriented language programs need to address short-term communicative needs or focus on improving specific skills, this should not be at the expense of providing learners with the ability to understand and control the systems underlying not only how but also why language is used in the way that it is. Whatever curriculum framework or goals are adopted for a workplace program, therefore, it is essential that attention be paid to how grammatical choices contribute to meaning, and thus to a need for a focus on grammar. Without this, learners will struggle to acquire the creative control that they need in order to generalize their language learning and transfer their language skills to other contexts and situations.

However, grammar teaching still has not completely shaken free of its checkered past, and hangovers from previous unimaginative, context-poor approaches to pedagogy still color attitudes to its place in workplace programs. This is a pity, since grammar is not only fun and relevant to workplace language goals, but also vital to a pedagogy of empowerment.

Grammatical Variation in Adolescent Language

ANNA-BRITA STENSTRÖM

Introduction

Language change is unavoidable, and affects grammar as well as vocabulary and pronunciation. It “occurs when one group consciously or unconsciously takes another as its model, and copies features from its speech” (Aitchison, 2001, p. 83). What is involved is not simply a change from old to new patterns, however. Language change involves variation in that old and new patterns coexist for a certain period of time before the new pattern takes over. An obvious example of grammatical variation is French negation, conventionally expressed by *ne + pas*, but where the particle *ne* tends to disappear so that *je ne sais pas* ‘I don’t know’ exists side by side with *je sais pas*.

Undeniably, adolescents are the real trendsetters in today’s society, where being young is something to strive for when it comes to language, as well as in relation to clothing and lifestyle. The language used by adolescents in metropolitan centers is particularly interesting, since innovations tend to spread from there to the periphery. A recent example is the Spanish pragmatic marker *en plan* used as a quotation marker, equivalent to the British English *like*, which was first observed in the language of Madrid adolescents and did not appear in the province until a couple of years later.

Clearly, grammar is far less exposed to change than vocabulary, but when it does change, the new tendencies are generally first observed in adolescent conversation, which is characterized by simplified syntax, nonstandard verb forms, sentence fragments, and an abundance of pragmatic markers; these are all representative of conversational grammar in general, but are found much more frequently in adolescent conversation. Conversational grammar should not be regarded as “bad,” however. The nonstandard use of *go* in the form *I goes*, for instance, cannot simply be considered bad grammar, since it helps the speaker save processing time as an example of ‘pronominal symmetry’ (Rühlemann, 2008).

In this entry, grammatical variation will be discussed as it appears in adolescent language in terms of grammaticalization, syntactic simplification, and intensification. For lack of a large-scale variety of corpora of adolescent conversation, most of the examples are from British English and peninsular Spanish, as represented in COLT (the Bergen Corpus of London Teenage Language; see Stenström, Andersen, & Hasund, 2002) and COLAm (Corpus Oral de Lenguaje Adolescente de Madrid), both of which are accessible for research online (<http://gandalf.aksis.uib.no/colt> and <http://gandalf.aksis.uib.no/cola>). Examples from other languages will be provided to the extent that mention is made either in the literature or in articles on the Internet.

Grammaticalization

Much of what is going on in adolescent conversational grammar is the result of grammaticalization. A definition suggested by Androutsopoulos (2000, p. 158) includes “not only the development of grammatical items from lexical ones, but also their development

from existing grammatical material, as well as word order changes and the fixing of syntactic patterns," a definition that will be adopted here.

A typical result of grammaticalization is the development of quotation markers. They all express reported speech without an explicit verb of saying, a tendency that appears to be a crosslinguistic phenomenon of adolescent speech. The use of *be like* in this function, which was apparently first adopted by middle-class Californian girls (Romaine & Lange, 1991), has spread not only from the USA to Canada, where it is the most used quotative among young speakers, females in particular, but also to England, Scotland, and further. This usage is a phenomenon shared by boys and girls in the London vernacular, while Macaulay (2001) observed that, in Glasgow, the boys preferred *go* in this quotative function. In addition to *be like* and *go*, he mentions the use of *go like that*, *be like that*, and simply *be*. His hypothesis regarding the historical development goes as follows: *go* > *go like that* > *be like that* > *be like* > *be*, based on findings in the Glasgow area (2001, p. 16). By contrast, the only forms used by the London boys and girls in COLT are *go* (*she goes, I knew Laurie*) and *be like* (*and I'm like, and I'm like, scum!*). The recently discovered expression used as a quotative marker in the Madrid adolescents' speech, *en plan* (*y yo en plan, qué es esto?* 'and I like what's this?'), turned out to be a typical female feature (Stenström, 2006). German adolescents have adopted the single word *so* (*und ich so: cool! and er so: hä?* 'and I said: cool! and he said: what?'), while young Swedes use *ba* from *bara* 'just' (*han ba, du kan ju ringa* 'he just you could give a ring').

Another fairly recent example of grammaticalization is the development of the Swedish noun *typ* 'type' into a pragmatic marker meaning '(something) like' (*han är typ studentrepresentant* 'he is like a student representative'). Interestingly, the same use of the word *tipo* was discovered in the Madrid youth vernacular (*es rock español pero tipo Mago de Oz o algo* 'it's Spanish rock music like Mago de Oz or something'), the difference being that Swedish *typ* can be added as an afterthought (*hon är socialarbetare . . . typ* 'she is a social worker . . . or something'). Corresponding examples in French are *il s'est fait casser la gueule façon* 'he has got a beating like' and *c'était un sport genre marrant* 'it was a sport kind of ridiculous'.

In the sections that follow there will be several cases of grammaticalization, for instance in terms of generalization and reanalysis, as well as numerous borderline cases. These will not be discussed, however, for lack of space.

Simplification

Simplification is an important ingredient in adolescent speech but, as Reppen (2001, p. 198) puts it, while "adults use a greater variety of linguistic resources and combine those resources in different ways . . . students accomplish the same purposes with a more limited set of resources."

The Sentence or Clause Level

In adolescent conversation, speaker turns tend to be short with sentences consisting of a simple clause, a fragment, or a single word. Narrative sequences, on the other hand, contain longer sentences, where discourse and pragmatic markers usually serve as cohesive and bonding devices. Overall, coordination is the predominating sentence pattern.

In French young speech there is a tendency to simplify syntactic patterns to avoid complex (redundant) grammatical rules. Sourdöt (1997) points to the use of the same questioning strategy regardless of question type, as when the direct form *qu'est-ce que* is used instead of the indirect form *ce que* in indirect questions, as in *Je ne sais pas qu'est-ce qu'il a fait* instead of the grammatically correct *Je ne sais pas ce qu'il a fait* 'I don't know what he has done'. The London boys and girls substitute regular question tags either by

the invariant tag *innit*, or more often *yeah* (*You've read this book called Roll of Thunder, yeah?*). In Androutsopoulos (1997), which has provided all the German data in this article, it is reported that German adolescents tend to place the verb in non-final position in clauses beginning with the conjunctions *weil* and *obwohl*.

The Phrase Level

The noun phrase

Some nouns are exposed to a change of category. One is the Spanish *cañon* 'cannon', when serving as a postposed adjectival modifier (*María es una tía cañon* 'Maria is a fantastic girl'), and the Swedish *kanon*, with *kanon* in subject-complement position (*Maria är kanon* 'Maria is fantastic'), in either case a recent phenomenon. Other examples are taboo nouns in adjectival position (*I'm crap at cricket; It's a shit school*).

Examples of nonstandard English are the use of the demonstrative pronoun *them* as a premodifier (*where did you get them boots from?*), the irregular use of the prop word *one* (*yeah but my ones, my platforms are out*), and the irregular form of reflexive pronouns (*they know how to defend themselves*).

What seems to be a general phenomenon in adolescent language is the use of so-called "general extenders" (Overstreet & Yule, 1997), items that replace nouns that can be understood from the context: English *and/or stuff* (like *that*), *and that*, or *whatever*; Spanish *y todo eso* 'and all this', *o algo* 'or something'; German *und/oder etwas* 'and/or something'; Swedish *å sånt där* 'and something like that', *eller nåt* 'or something'; and so on.

The adjective phrase

Spanish adjectives are sometimes used as nouns (*El anormal este que . . .* 'This abnormal [situation] that . . .') and even as adverbials, for instance *bonito* instead of *bien* (*canta/baila bonito* 's/he sings/dances well'). The adverbial use is also observed in French youth language, as in *Je le kiffe grave* instead of *gravement* for *Je l'aime beaucoup* 'I like him a lot', which typically reflects an effort toward simplification (Sourdöt, 1997).

In German youth language adjective inflexion is avoided by means of borrowings from English (*mit der fucking Hausarbeit beschäftigt* 'busy doing the fucking homework'). In substandard youth speech, even domestic adjectives tend to be uninflected. Overall, there is a language typological drift toward English in German adolescent speech.

The adverb phrase

Change of category also affects adverbs used as adjectives. This is observed in the Madrid vernacular (*Vete a ver "la Roca" que está fenomenalmente* 'You should go and see "La Roca" it's great'), where the adverb *fenomenalmente* is used as a subject complement, and a similar tendency is observed in French (*ce type il est trop* 'this guy he's too much').

Aijmer (2008) demonstrates the development of *obviously* from an evidential adverb into a pragmatic marker and of the epistemic modal adverb *definitely* into an intensifier in the London teenage vernacular. Also worth noting is the use the adverb *well* as an adjective intensifier (*well cool/good/weird*, etc.), a usage that has spread to the adult population, and the placement of *enough* before the modified adjective (*it's enough good*) instead of after it, as in the standard language.

The verb phrase

A typical feature of London adolescents' speech is the use of reduced verb forms (e.g., *dunno*, *wannit*, *dunnit*, etc.). Other examples of verb-phrase simplification are the missing auxiliary in *so you 0 seen him round the school*, irregular use of the Q-tag (*sounds good to you don't it*), past participle for imperfect (*this is the one we done last night*), irregular verb forms

(*I ain't wore much of my platform to school*), active for passive (*it's meant to wear like this*), and irregular tense forms in conditional sentences (*if we'd have left early we still could . . .*). Nonstandard past-tense forms such as *seen* and *done* and invariable *don't* have also been observed, in Australian youth speech for instance (Eisikovits, 1998, p. 43).

Another example is "pronominal symmetry," where the same verb form is used regardless of person, as in *I says, she don't*, and so on. Cheshire and Fox's recent study of London English (2009) points to a variable pattern of leveling to *was* across person, number, and polarity (*you was, we wasn't*, etc.) and *were* in clauses with negative polarity (*It was still good, weren't it*). French adolescents, too, tend to simplify the verb conjugation, reducing the temporal system to present, future, and *passé composé* (perfect). A change of construction is represented by the intransitive use of transitive verbs, as in *il assure, ça craint* ('he assures that this is dangerous').

A recent trend in Spanish youth speech that is spreading is to replace *ser* with *estar* for permanent qualities (*está tope de buena* 'she's super'). Moreover, verbs used as transitive in the standard language are used with a new significance with *se* 'oneself' attached (e.g., *atacarse* 'get nervous'), and there is a predilection for reflexive constructions (*Ya te has hecho otra página?* 'Have you made a new Web page yet?'; see Herrero, 2002). In addition, transitive constructions with a direct object, such as *pegar* 'hit', are often replaced by verb + *de* (e.g., *dar de: dar de puñetazos* 'give punches'). Similarly, in German youth language, there is a growing use of constructions using *tun* 'do' instead of other verb constructions.

The prepositional phrase

Simplification often leads to reduction. Take for instance the loss of the preposition *of* in *he looked out 0 the window*. A frequent example of prepositional reduction in Spanish youth language is the so-called "quéísmo," where *que* alone is used instead of *de que* (*Tuvimos suerte 0 que no nos pillaron* 'Fortunately, they didn't get hold of us'). A type of prepositional simplification that occurs in German adolescent language is to let the prepositions *wegen* 'because of' and *während* 'during' be followed by a dative instead of genitive nominal construction in line with *mit* 'with' and *zu* 'to'.

Negation

Negation attracts simplification as well as multiplication. A typical example of simplification, mentioned in the introduction, is the widely spread French *ne*-dropping, as in *je sais pas, il faut pas*, and *je crois pas* instead of the correct forms *je ne sais pas* 'I don't know', *il ne faut pas* 'one shouldn't' and *je ne crois pas* 'I don't think'. This usage is by no means restricted to adolescent language, though this is where it is likely to be most frequent. Today, *ne* is used so seldom in many varieties of French that the question is no longer when and why it is deleted, but when and why it is used. Today, *ne* is considered to be a device used for emphasis, signaling a particularly strong negation, rather than simply a negative particle.

As regards simplified negation in other languages, London adolescents sometimes replace a negative *do*-construction simply with *never* (A: *You did*; B: *No I never*), while German youth tend to use *null* 'zero' and *nix* 'nothing' to avoid the inflected form *kein* /*e*.

Intensification

The need to put extra emphasis on a message is a predominant feature of adolescent speech style. This is emphasized by Herrero (2002), who argues that the information structure in adolescent conversation has two aims: to be as efficient as possible and to facilitate information processing. A frequently adopted intensifying strategy is fronting, as in *The*

books you can give them to me tomorrow, where the object is moved to the front to achieve prominence, or *How clever you are*, where the subject complement is moved to the front. Fronting is probably a universal phenomenon, typical of conversational grammar in general.

Although taboo and swearwords are by no means unique to adolescents, adolescents tend to use them as intensifiers more frequently than adults do. Taboo expressions are often inserted without forming part of the syntactic structure, as in *What the hell is it?* with special emphasis on the verb, and *Y yo estaba de puta madre con él* 'I was for fuck's sake with him', with the emphasis on the prepositional phrase *con él*. Or they can be integrated in the syntactic structure as adjectival and adverbial modifiers, as in *it's a bloody microphone* and *it's bloody awkward*, or inserted in a word, as in *unfuckingtouchable*. *Fuck/ing* is a particularly versatile intensifier in terms of syntactic function, more so than other taboo intensifiers, which partly explains its frequency (*she's a right fuck*; *fucking disgusting*; *a fucking sexist*; *I fucking hate him*, and so on).

London adolescents (girls in particular) have a predilection for the intensifier *really* (*really massive*, *cool*, *pissed-off*). A popular intensifier among non-English adolescents is *super*, which turned out to be used much more often by Madrid than London adolescents. Other common intensifiers in Spanish young speech are the slang expressions *mola* 'I like it a lot', *guay* 'excellent', and *mazo* 'much'. In German youth language there is a predilection for fairly 'regular' intensifiers (*echt*, *total*, *wirklich*), while the adjectives *grym* 'cruel', *sjuk* 'sick', and *fet* 'fat' have recently been adopted as intensifiers by Swedes.

Negative intensification is expressed by negative polarity idioms such as *I don't give a damn/fuck/shit* by London teenagers. Corresponding expressions are likely to be found in youth language overall. In addition, there are frequent examples of multiple negation, such as *They didn't say nothing*, *Mum don't have to do nothing* (with invariable *don't*), and the even more complex construction *I ain't telling you no more cos I don't know none* (Palacios, 2011).

A frequent way to intensify the contact between the speakers consists in using "contact checks," such as English *look* and *listen* and the Spanish very frequent equivalents *mira* and *oye*. Probably even more efficient are the German *aber hallo!* and the corresponding Swedish *men hallå!* Vocatives, too, have an intensifying effect. They are extremely common in Madrid teenagers' speech, but are comparatively rare in London teenagers' speech (see below). By and large, the relative shortage of vocatives uttered by London boys and girls is substituted by their frequent use of *you know* as a kind of attention-calling and bonding device.

Gender Differences

The most salient exponent of grammaticalization in English and Spanish adolescents' language seems to be the use of *be like* and *en plan* as quotation markers (see above), both of which dominate in the conversations of girls.

As regards simplification, the most noticeable feature in the talk of London teenagers is the frequent use of the contracted forms *ain't* (boys) and *innit* (girls), followed by negative concord, used almost equally often by both genders, and the less frequent multiple negation, used by girls alone. Another typical feature is the replacement of regular question tags by the invariant forms *innit* (boys) and *yeah* (girls). Overall, London girls use the largest variety of nonstandard grammatical features, while boys adopt certain nonstandard features more frequently. Common to both English, in particular, and Spanish girls is the more frequent use of simplification realized by general extenders (e.g., *and everything*, *y todo*). In the talk of Madrid teenagers, one notices above all the tendency to use category shifts involving adjectives and adverbs, which seems to affect both genders with no apparent

difference, and the recent trend to replace *ser* 'be' with *estar* 'be' for permanent qualities.

Intensification by adjectives and adverbs dominates in the speech of girls in both corpora, in particular English *really* and Spanish *todo* 'completely', though the boys tend to use the strongest items. Intensifying taboo expressions predominate in the Madrid teenagers' talk, in the boys' talk in particular, while the girls dominate among the London teenagers. When it comes to swearing, the boys dominate in both corpora, both in terms of frequency and in terms of strength. The three most common taboo words in COLT represent the three typical domains of sex, religion, and excretion, while those in COLAm are restricted to the sexual domain.

What distinguishes the two corpora even more is the frequency and impact of vocatives. The female vocatives dominate in COLAm, especially *tía* 'girl' and (to a much lesser extent) the male vocatives in COLT (e.g., *man*). The fact that vocatives are far more common in the Madrid teenagers' speech overall seems to point to their more intimate and involved style.

A challenging and intriguing question to be considered in the future is the impact of the reduced style of e-mail and SMS messages and the contact with ethnic minorities on the development of adolescent grammar and its influence on the standard language.

Grammar in Academic Writing

PHILIP M. SHAW

Academic discourse (the language, organization, and rhetoric of academic texts) is a member of a set of discourses called “language for specific purposes” (LSP), which include business, legal, and technical discourse. These discourses occur in spoken and written texts of many sorts. Their vocabulary and grammar can be called their registers, so that one could speak of a general academic written register characterized, for example, by formality and precision, and, within that, of the register of chemistry, characterized above all by a particular terminology. But all these LSP discourses are also characterized by having a particular set of genres (i.e., types of texts with a particular purpose and audience, for example textbooks, research articles, student essays). They use the grammar of the general language but the frequency and functions of some features are different, depending partly on the genre.

Earlier research tended to look at “languages for science and technology” (Trimble, 1985; Hoffman, 1985) as a whole and identify grammatical/lexical features of a generalized register without reference to their functions in a particular context, but since the 1990s studies of academic writing have tended to examine the vocabulary and grammar of specific genres in specific disciplines (Swales, 1990), and very often from the perspective of their pragmatic or rhetorical functions. There has recently been considerable interest in the phraseology of academic writing, that is, the way words co-occur with one another, but, like research focused on word choice, this is not discussed here.

Written academic texts can be divided into the categories of research genres (articles, monographs, abstracts, proposals, etc.), learner genres (essays, exam answers, reaction pieces, etc.), and educational genres (textbooks, Websites, lab instructions, etc.). Texts in all three categories can be divided by discipline: each discipline has its own conventions and style and a common core of terms and other register features. There have of course been immense changes of genre and rhetoric over time. Many disciplines in all languages share a broad rhetoric which can be traced back to the rise of scientific writing in modern Western languages (as opposed to Latin) in the 17th century (Valle, 1997). The discourse of modern scientific research writing in this tradition aims to create the impression that the writer “lets the facts speak for themselves” in a modest, impersonal, unemotional way (although this effect requires a particular rhetoric and manipulation to make the intended points). The focus here is on the language of writing by researchers for their peers (research genres) in this modern tradition.

Hoffman (1985) gives a list of characteristics of special-purpose language focusing on academic writing (and many typical of expository writing in general), with examples from Russian, English, French, and German. It includes predominantly crosslinguistic formal features, with some functional, including a restricted set of tenses and somewhat specialized functions for them, predominance of the third person of verbs and specialized uses of first person *I/we*, frequency of the passive voice, deverbalization (that is finite verb expressions are relatively less frequent and participle phrases, nouns, and adjectives replace them), specific functions of modality (*can be used*, etc.) as expressions of “hedging” (moderating the confidence of an expression), and complex nominals including a high proportion of nongradable adjectives (English, French, Russian) or compounds (German). To this can be

added explicit cohesion and a restricted range of sentence types with only specialized interrogatives and imperatives used to create engagement with the reader (see below). In a different theoretical context, Halliday (1993) distinguishes between a dynamic style with complex clause patterns (many coordinated and subordinated finite clauses), simple phrase structure and low lexical density, and a synoptic style with rather few finite clauses, complex phrase structure, and high lexical density. The style of academic writing is synoptic.

As noted above, attention has shifted to the functions of the features of academic writing within the genres where they occur, either in the empirically oriented tradition of Swales (and Bhatia, and especially in the 2000s of Hyland), or within systemic-functional theory (Halliday, 1993). Some functional categories are pervasive features like expressions of writer stance and engagement, such as hedging (*it is perhaps the case that, we might suggest that*), others are more local ones like reference (*Schmidt (2003) suggests that . . .*) or knowledge claim (*We therefore suggest that . . .*). There are also moves in genres like “indicating the gap,” which is typical of the introductions to academic articles and states something like *as yet no one has investigated X* or *there has been little research on X*. These can have many grammatical/lexical exponents, and similarly grammatical/lexical categories like “modal verbs” or “personal pronouns” can perform several functions, so that mapping one to the other is not easy. If we search for instances of *suggest/propose*, and so forth, we will come up with a grammatically fairly uniform set of instances, but some will exemplify reference while others will exemplify knowledge claim.

Within research writing the main attention has been on the research article in the natural sciences and medicine. In 2010 such writing was mostly in English, but many of the characteristics of academic language are similar across languages (including Chinese and Japanese; see Mohan et al., 2007), because science has always been an international activity. Differences among the rhetoric of different languages may come partly from differing national traditions (Kretzenbacher, 2001) or audiences but are largely due to different linguistic resources to express the same general pragmatic purposes. Thus Fløttum, Dahl, and Kinn (2006) contrast one particular resource for impersonal expression in three languages: the availability in French of the multiply ambiguous generic pronoun *on*, in Scandinavian languages of the everyday unmarked but referentially more restricted generic *man*, and in English only of the stylistically marked and rather infrequent generic *one*. Work on articles in English (mainly) as a second language seems to show that both rhetoric and grammatical features can be transferred from the first (or another familiar) language to another language in which one is writing, but this is almost always confounded with differences in the size and nature of the audience aimed at, so that claims of transfer of rhetoric are not uncontested (Burgess, 2002).

In general, the grammatical features of the language of scientific research articles and theses which have attracted attention are those that reflect the aims and conceptual patterns of the disciplines to which were contributed. The features are not usually unique to these genres or disciplines but merely of different frequency in research writing by comparison with other registers. In an attempt to describe features of academic writing in several languages, reference is made here to the extensive work in German on *Fachsprache* (much of it at the register level; see Kalverkämper & Baumann, 2010), and to work on French and Spanish. A high proportion of academic writing nowadays, however, is in English and this justifies giving most attention to this language.

Noun Phrase Characteristics

Academic writing is often in Halliday’s synoptic mode, hence noun phrases are mostly complex with extensive pre- and postmodification, and their heads are often nominaliza-

tions expressing processes or qualities, whereas sentence patterns may be relatively simple. A common pattern is the development of such complex nominals so that a concept introduced as *The high power density of lasers permits the surface melting of many materials* (itself a good example of complex noun phrases in a simple syntactic structure) can later be recalled encapsulated as *laser melting* (Bhatia, 1992). The noun phrases may include pre-modifying nouns and postmodifying prepositional phrases but particular attention has been given to reduced relatives of the type *the energy levels displayed in the hyperfine transitions*. Vande Kopple (1998) associates finite relative clauses with less established concepts that may need tense and modality for full expression, and nonfinite (reduced) clauses with well-established concepts that only need to be referred to. Research in pioneering spectrometry, he found, was reported in more dynamic terms, while in modern spectroscopy the style is more synoptic.

Personal Pronouns

Complex nominals and thematization patterns are, broadly, expressions of the subject matter of the text. Alongside this there are manifestations of interpersonal meaning, characterized by Hyland (2005) as engagement (features that manipulate the reader's involvement in the text, including rare uses of *you* and common uses of a *we* that includes the reader) and stance—features that express the writers' attitude to the content presented namely hedgers, boosters (*clearly, obviously*), attitude markers (*unfortunately, hopefully*), and self-mention. This last refers to language which replaces the prevalent impersonality of academic writing with more personal expressive devices, for rhetorical effect. Self-mention is often used as a way of highlighting and differentiating original contributions and decisions. The issue of author presence is complicated because the effect, whether of stance or involvement, depends on five variables: reference of *we*, date of publication, language/culture, number of authors, and discipline. Different uses of *I/we* evoke different degrees of "author presence" in the text (Harwood, 2005) so that inclusive *we* ("we humans," "we researchers," "we scientists," including the reader) used for logical argumentation creates engagement but is quite nonintrusive in terms of stance, while an exclusive *I* or *we* used to claim a new finding is a bold rhetorical move. Earlier dates of publication tend to mean fewer personal pronouns academic writing, since broadly speaking research writing is becoming more personalized across cultures and disciplines. The effect of language or culture seems to be that papers in English are leading this trend toward a more personal style, so single-authored papers in English tend to have more instances of *I* than those in German, and these more than French, with single-authored Russian (and Bulgarian) hardly using *I* at all (Vassileva, 2000). However writers in French, Russian (Vassileva, 2000), and Spanish (Martín-Martín, 2009) are much more able to use the equivalent of *we* for a single writer than users of English and German. Single authors are common in the humanities and rare in the hard sciences, so *I* is less frequent, and perhaps more marked, in hard science for this reason alone, but usage and editorial policy differ across disciplines within these broad fields. It should be noted that use of *you* and of directives and questions is much more common in educational genres like textbooks, reflecting the greater need to ensure the engagement of the reader in these genres.

Tense

Academic writing tends to use a limited range of tenses and aspects in all languages, as Hoffman (1985) noted, and to use these tenses in special ways. Rather like pronouns, tense choice can be used to create immediacy for one proposition and distance for another.

4 GRAMMAR IN ACADEMIC WRITING

Liddicoat (2004) notes, for example, that the subjunctive and the past simple are both extremely rare in French scientific writing. Most verbs are in the present tense and nearly all the rest in the past (*passé composé*). Accounts of procedures were normally written in the present and a switch to the past indicated a particular decision of the writer, or in accounts of other researchers' work, backgrounding to suggest lower relevance. Conventions for tense usage varied somewhat across the sections of the articles (a frequent finding in several languages) (Swales, 1990). In English the present (mainly) and the present perfect co-occur in discussions of the current state of knowledge in introduction and discussion sections, while the past is more frequent in method and results (Biber, Connor, & Upton, 2007). Liddicoat concludes that effects of foregrounding and backgrounding are not so much inherent in verbs forms as results of choosing a form which is marked or unmarked in the context of neighboring tenses. Findings about the significance of tense choice show that it is very dependent on the lexical verbs involved and the function of the text section examined (Swales, 1990), but one can say that in English the past seems to be used to refer to specific results and procedures, and elsewhere to indicate less immediate relevance, while the present and present perfect indicate greater generality, greater immediate relevance, or both.

Thematization

The theme in a sentences is an element that is prominent because it comes early. It is often a realization of the topic. Thus in *Jane saw him today*, *Jane* is thematic, but in *Today Jane saw him*, *today* has been thematized. In academic writing it is common to thematize the object of study (often as a complex nominal) rather than the actor, both to achieve an impersonal effect and to structure the text around its key content. This can be achieved by using the passive voice, which is the unmarked pattern for actions in academic writing, as in *The liquid was heated*, making *the liquid* the topic of the sentence. A related thematization feature available in English is the use of the active voice with a nonanimate subject *This thesis argues that*, *The graph shows that . . . calculation shows*, a type of metonymy. Both devices de-emphasize agency where it is not rhetorically useful. Thematization is used as ways of structuring the text according to disciplinary aims and needs: it has been shown that thematized material (often grammatical subjects, whether of active or passive verbs) varies considerably across disciplines (Gosden, 1993; Gunnarsson, 1997) and even subdisciplines (MacDonald, 1994). Strategic use of impersonality enables writers to focus attention on facts or, exceptionally, to use personal reference to highlight their own contribution (Tarone, Dwyer, Gillette, & Icke, 1981) as in *we argue that . . .*

Cohesion

Cohesive devices in academic writing are of course members of the same set as those in other formal writing, but some items may be more frequent in the general register or in the register of a particular discipline, and explicit cohesion may be especially important. A general finding is that logical connectors like *therefore* are somewhat less frequent in research writing than in student or educational texts, presumably because in the latter categories it is important to make causal and other logical links explicit to display one's knowledge or to help novices, respectively, while in research writing one can presuppose knowledge of likely relationships. Complex nominals probably play an important part in cohesion instead. Nominals like *this complicated issue* that refer to (the content of) a stretch of text, that is not referring to a previous instance of *issue* (Francis, 1994) are called retrospective labels. They have numerous functions: textual, in marking coherence between a

previous string and the present one; evaluative, in allowing the writer to express a stance toward the content, as important or difficult or much-discussed, for example; and ideational, in that many of the labels allow the writer to characterize a set of propositions as *behavior* or *projects*.

Moreno (2004) looks at expressions of result or logical consequence in English and Spanish academic writing on business. She arranges a number of different structures on a scale of explicitness. The most explicit are retrospective labels. Then she has “fuzzy” retrospective labels like *this* unspecified by a lexical item, and implicit labels without any realization: these are either conjuncts (*therefore*) or expressions, like *the implication is* or *we may conclude*. In both languages implicit labeling was twice as frequent as explicit, and in other ways too, the distribution of resources was similar across languages. There was some tendency to greater precision and more personal evaluation in the English link, as found in other studies of other features.

Hedging

The interplay of functional, semantic, and grammatical-lexical categories is well illustrated by the case of the function “hedging,” the semantic notion “epistemic modality” (the use of modal verbs and adjectives to indicate how certain or true something is), and various grammatical categories, such as adverbs, modals, and verb phrases which can express it. *Perhaps X is Y* and *It may be suggested that X is Y* use different realizations of epistemic modality to hedge the confidence of *X is Y*, while *X is roughly Y* uses a realization of approximation to do something similar. The category is important because one of the main difficulties in academic writing is to adjust the strength of the claim, to make it as strong as possible while maintaining credibility and approval in the eyes of the peers who are reading it. Vold (2008) and Martín-Martín (2009) show that hedging by means of approximation and epistemic modality is more frequent in English-language articles than in Spanish or French, conceivably reflecting a larger and more critical audience.

Intertextuality, Citation, and Knowledge Claims

The essence of research writing is that the current text is explicitly linked to other texts, extending, confirming, or disconfirming their findings. The textual reflection of this feature of the scientific process is intertextuality. This has attracted research attention because practices and the lexis used vary widely across disciplines. Intertextual references can be made (A) with or (B) without a reporting expression of some kind, and if a reporting verb is used the author’s name may (B1) or may not (B2) be integrated into the sentence. Examples are:

A: *Weights vary between 1 and 5 grams (Schmidt, 2003).*

B1: *Schmidt (2003) found that weights varied between. . . .*

B2: *Weights have been found to vary. . . (Schmidt, 2003).*

In the hard sciences type A predominates, in the social sciences and humanities type B1 is much more common, reflecting the way knowledge is constructed in the disciplines. Both the tense of the reporting verb and the lexical verb chosen can indicate the writer’s stance toward the finding reported. Verbs like *argue* in the present are more common in political science than in materials science (Charles, 2006); verbs like *find* in the past show the opposite pattern. The same set of forms is used to make the author’s own knowledge claims (do the results *show* something or just *suggest* it?) and in the hard sciences the choice

of a lexical verb to define one's own knowledge claim (rather than to qualify others') is crucial.

As this survey of some features that have been discussed shows, much attention has been paid to stance and engagement, that is, to personal and interpersonal functions of the language of academic writing. The challenge for the future is to tackle linguistic manifestations for the particular ways of thinking of the disciplines in a way that will help learners acquire and practitioners understand explicitly the language that structures and is structured by their thought patterns.

Grammar in Language Teaching and Education

TAMMY SLATER AND JINRONG LI

If we were to open up a dictionary and begin reading, it would be obvious that despite our ability to construct meaning from the words on the page, we would not be able to interact with the writing in the same way as we do for other texts. Dictionaries do not use grammar in the same way as we typically use it for communication. Language users manipulate the grammar to construct experience in particular ways for particular purposes, and language education throughout history—both second and foreign-language teaching—has acknowledged this by including some form of grammar instruction in its curriculum. Research has revealed that contemporary language teachers and learners share an overwhelming belief in the importance of grammar study for successful language learning (e.g., Borg & Burns, 2008; Jarvis & Szymczyk, 2010). Yet as Ellis (2006) argued, issues around the teaching of grammar have continued to plague the field of second language education. This entry presents a chronology of grammar teaching, noting the constant back-and-forth movement between deductive/explicit and inductive/implicit approaches, an issue that continues to be at the center of much research today. Moreover, given the continuing growth of technological innovations, we will also look at the role that technology has played in the teaching and learning of grammar.

Before embarking on a discussion of grammar in language teaching, however, it would be useful to define what we mean by “grammar.” Since the end of the classical period, the term has shifted in meaning and usage from its initial focus on writing and the art of letters to its current reference to the *rules* of language, language form. As an examination of language-teaching textbooks over the years will confirm, these rules have played a critical role in teaching language, both by appearing as explicit statements that students must learn and practice, or in lessons which aim to help the learner form rules from the input.

Some of the earliest words on grammar in language teaching, those of St. Augustine, suggested that having a practical command of a language was more important than the memorization of grammatical rules. St. Augustine advocated the use of dialogues through which language learners could discover the patterns (Kelly, 1969). Throughout the Middle Ages and into the 19th century, there was regular movement between presenting grammar rules for practice, based on the grammatical analysis of Latin and Greek (focusing on the eight parts of speech: nouns, verbs, participles, articles, pronouns, prepositions, adverbs, and conjunctions), and teaching through more inductive presentations of grammar, through reading, speaking, and imitation, to allow students to internalize the patterns for practical use. These two perspectives clashed even within similar time frames. In 1506, for example, Comenius drafted works that reflected a primarily inductive approach to language learning, yet in 1520, Erasmus insisted that formal grammar teaching was necessary in the beginning levels, albeit he conceded that advanced speakers could be taught using more inductive methods. Thirty years later, attacks on the teaching of grammar again appeared in the writing of Lubinus (Kelly, 1969). This back-and-forth movement between teaching inductively or deductively (or implicitly versus explicitly) was to continue throughout the centuries.

In the late 18th century (1780s), lasting well into the 20th in some areas, learning a foreign language involved analyzing the grammar of that language, memorizing the rules, and applying those rules in translation. The emphasis was on the written form of the language with little or no time spent on oral skills. This *grammar-translation method*, as it came to be known because of the two features that critics most disliked about it, originated in Germany (Richards & Rodgers, 1986; Howatt, 2004) with the best-known courses those of Ollendorf in the 1840s (Kelly, 1969; Howatt, 2004). The method involved the presentation of a grammar rule, a short list of vocabulary, and items to be translated for practice. Later in the 19th century, Karl Plotz strengthened the hold that the grammar-translation method had on language education, moving from authentic texts to passages that were constructed to match clearly and unambiguously the rules and vocabulary being presented (Kelly, 1969). This approach to language teaching has persisted in this format through to the present era in many countries (Richards & Rodgers, 1986; Brown, 2001; Hinkel & Fotos, 2002).

Late in the 19th century and into the 20th, the pendulum began to swing back to inductive grammar teaching as the *direct method* of language instruction became popular. This method, its name often used synonymously with the *Berlitz method*, was characterized by its exclusive use of the target language in teaching. The belief was that languages should be learned in a fashion similar to the way the first language is acquired, and translation, in opposition to the previous ideas of language study, was deemed unnecessary. Grammar was not presented deductively as rules but was made evident through the patterns and progression of the material, and learners acquired the rules of grammar inductively through imitation, repetition, speaking, and later reading (Howatt, 2004).

In the early 20th century, linguistic analysis moved away from the eight parts of speech that had been used for teaching and analyzing Greek and Latin to structural or descriptive linguistics, which analyzed language through its phonology (the sound system), morphology (the smallest meaningful combination of sounds), and syntax (the combination of units of communication). With this shift, along with the influence of behaviorist psychology, the *audiolingual method* (ALM) was introduced to the language education scene in the 1950s (Kelly, 1969; Hinkel & Fotos, 2002; Howatt, 2004). The emphasis of ALM was on oral skills; speech was to come before writing, with grammar rules learned inductively through pattern drills comprised of basic conversational sentences that the students were to memorize as accurately as possible. With the vocabulary load controlled and the patterns graded for teaching progression, the rules of grammar were to become a set of habits that could be acquired through stimulus and response techniques. Reinforcement when the student was successful as well as immediate and thorough feedback for the correction of errors were considered critical to ensure that mistakes would not persist.

Reacting to the very behavioristic practices of ALM and influenced by Chomskyan views on the nature of language as rule-governed, language educators once again moved toward the teaching of grammar deductively. The *cognitive approach* to language learning held that learners needed to know only a basic number of grammatical rules to create and understand sentences. The idea was that speakers have access to a universal grammar (UG), which all humans are born with. The parameters of this UG are set during the acquisition of the speaker's first language as a result of input. The language curriculum therefore had to identify the properties of grammar that would allow learners to reset the parameters of their UGs, if necessary, so that they could make generalizations that would result in correct grammatical utterances in the target language. Grammatical consciousness-raising was encouraged so that learners would understand the rules, and explanations of the target language grammar in the learner's first language were accepted.

Beginning at about the same time, in the 1960s, *notional/functional syllabuses* appeared, which organized grammatical content on the basis of what was needed to fulfill certain

communicative functions or situations, such as “Asking for help” or “At immigrations.” These syllabuses, which move from beginner (easy) to advanced (difficult) and range from highly controlled to the free production of the target grammar and vocabulary, continue to be reflected in many contemporary textbooks where various language-practice and grammar activities revolve around a communicative function or situation (Brown, 2001). Grammar is played down in favor of the function or situation, but with the recognition that certain grammatical forms appear naturally in certain situations, offering opportunities for specific grammar practice.

The next era, what Brown (2001) referred to as “the spirited 1970s,” spawned a collection of innovative language teaching methods that varied in their approaches to and presentation of grammar, although they all favored an inductive approach to teaching grammar. Five of the more popular methods are presented here (see Brown, 2001, or Richards & Rodgers, 1986, for more detail). Both *total physical response* and the *natural approach* made use of first language acquisition studies and placed listening comprehension first, offering input so that learners could internalize and acquire the language before having to use it. An understanding of grammar was thus developed inductively. *Suggestopedia* was another method that aimed to allow learners to determine the grammar inductively, by having them listen to large amounts of text accompanied by baroque music. The mind, according to the method’s creator, was more susceptible to learning and retaining information when it was in a relaxed state. The fourth method, the *silent way*, was a discovery-learning approach that involved cooperation and problem solving amongst learners with little input from the teacher. Learning a language was done by manipulating Cuisenaire rods and looking at charts of vocabulary and pronunciation. As with the previous three methods, the structure of the language was determined inductively through learner problem solving, with the idea that learner-driven discoveries are more meaningful and lasting than teacher-instructed ones. The fifth method from this era, *community language learning*, used translation and no predetermined content, and again grammar was gleaned through the input. The method placed the teacher in the position of counselor, with the learners determining the theme and content of any given session. Conversation was built up by the learners, with each individual adding to the conversation with a comment that the teacher would translate from the native language into the target language, and that the learner would repeat. The session was audiotaped, and together the learners attempted to discover the rules of the new language. Thus as with all the methods of the spirited 1970s, grammar teaching was done inductively.

The arrival of the 1980s brought an emphasis on *communicative competence*. Chomsky had used the term *competence* to mean “the speaker-hearer’s knowledge of the language” (Chomsky, 1965, p. 4) or “intrinsic tacit knowledge” (p. 140), distinguishing it from *performance*, which he defined as “the actual use of language in concrete situations” (p. 4). But from a social perspective, what people knew about language and what they did with it were very much intertwined. Sociolinguists such as Hymes (1972) thus argued in favor of including the notion of appropriateness within the definition of competence by stating that “there are rules of use without which the rules of grammar would be useless” (p. 278).

Out of this era, the theoretical framework for communicative competence, one of the most influential theories in the field of language testing, was proposed by Canale and Swain (1980) as an attempt by the authors to “establish a clear statement of the content and boundaries of communicative competence—one that will lead to more useful and effective second language teaching, and allow more valid and reliable measurement of second language communication skills” (p. 1). The framework emphasized

preparing second language learners to exploit—initially through aspects of sociolinguistic competence and strategic competence acquired through experience in communicative use

of the first or dominant language—those grammatical features of the second language that are selected on the basis of, among other criteria, their grammatical and cognitive complexity, transparency with respect to communicative function, probability of use by native speakers, generalizability to different communicative functions and contexts, and relevance to the learners' communicative needs in the second language. (p. 29)

Thus the framework brought grammar knowledge to the forefront of language acquisition and considered communicative competence to be the interaction and relationship between grammatical and sociolinguistic competence.

Along with the creation of this framework, and arising in part from observations that many English-language learners knew the rules of grammar but could not use them to communicate effectively (Hinkel & Fotos, 2002), *communicative language teaching* (CLT) arose. This approach aimed to move beyond grammar study and synthetic contexts to authentic language use in the classroom and beyond. Meaning became paramount, fluency was valued over accuracy, with grammatical explanation acceptable if it helped the learner learn to communicate (Brown, 2001), although explicit grammar teaching and error correction were initially not features of CLT (Hinkel & Fotos, 2002). The idea that learners could understand the meaning of the message and learn from it if the input is comprehensible and minimally beyond the learner's current ability became attached to CLT, particularly in immersion programs where language was taught alongside content. Through CLT, fluency became the goal in English as a second language (ESL) classrooms where the target language was being used to share and learn. Grammar thus once again took an inductive approach. Communicative tasks became the vehicle for teaching, with language teachers intervening in ad hoc ways to help with grammar correction as they noticed difficulties.

Despite success in developing fluency through CLT programs, research revealed that learner errors were not being attended to satisfactorily or systematically, and issues of fossilization—errors becoming permanently part of the speaker's language—surfaced, bringing a renewed interest in grammatical form, but one that could be approached in a meaning-centered way, compatible with the communicative approach. Research began to be carried out on the effectiveness of explicit grammar teaching versus a more implicit grammar instruction within the context of communicative tasks. Spada and Tomita (2010) conducted a meta-analysis to examine explicit versus implicit grammar instruction in an effort to inform educators about the types of grammatical features that would benefit from each. They concluded that explicit instruction was more effective with both simple and complex grammar structures, but noted that implicit instruction may simply take longer to be effective. Batstone and Ellis (2009) argued for both types, stating that learners must learn to make connections between grammatical form and the meanings that such forms signal, and that learning these mappings involves connecting what the learners already know to what they are learning, making the learner aware of the grammar being taught (see also Ellis, 2006), and giving learners opportunities to practice grammatical forms in a meaning-centered way.

Research has also been carried out on implicit teaching, in particular examining the role of corrective feedback in language development (see Sheen, 2010). Teaching grammar implicitly in the context of tasks can be done by offering either explicit feedback, feedback that lets the learner know that a mistake has been made, or implicit feedback, where the learner must infer from the feedback that his or her utterance is not correct. Implicit feedback is typically given through recasts, confirmation checks, and requests for clarification. In a meta-analysis of the effectiveness of corrective feedback, Li (2010) concluded that over the short term, explicit feedback worked better than implicit, but mirroring Spada and Tomita (2010), the author stated that implicit feedback was perhaps more effective over the long term.

The discussion so far has focused primarily on language learning through classroom-based, face-to-face interaction, but in recent years grammar learning and teaching have been shaped by *computer-assisted language learning* (CALL) applications as innovative technologies have become integrated into the language-learning processes (see Chapelle, 2009; Godwin-Jones, 2009). At its most classroom-based level, technology can offer language teachers interesting tools for teaching grammar either deductively or inductively. PowerPoint presentations, for example, can use animation, color, and other manipulations to make the grammatical form more salient to the learner, a necessary step in promoting grammatical accuracy as noted above. Web sites offer interactivity and interesting ways to access information and can be easily adapted and updated. In keeping with the view that second language acquisition (SLA) might be enhanced by the growing possibility of human-computer and human-human interactions, the idea grew that CALL activities could facilitate grammar teaching and learning in two main ways. First, they could create diverse and individualized opportunities for learners to interact with computer-based resources. With these resources, students who wish to focus on explicit grammar-learning independently would have, through technology, the opportunity for self-study using vast numbers of activities to make the practice more interesting. Second, CALL activities could be used as intermediate channels to help learners expand their communication with native speakers (NSs) and other non-native speakers (NNSs), providing a more implicit and communicative approach, a natural way of linking form and meaning. These two ways of using technology to teach grammar will be discussed below.

The resource-oriented approach started with online grammar tutorials and gap-filling or multiple-choice exercises created using authoring software such as Hot Potatoes. Despite criticisms of the mechanical nature of such materials, these resources continue to be regarded as important. There are also computer-based proofing tools such as grammar and spell checkers. Other tools, such as LanguageTool and AbiWord, have also been developed to handle a wider variety of languages and more advanced syntactic and semantic analysis and thus provide tailored feedback to help improve grammatical accuracy in writing.

The emergence of *natural language processing* (NLP) parsing technology has given rise to the development of intelligent CALL, or ICALL, which aims to provide more “differentiated” feedback based on learners’ interaction with the language-learning resources (Godwin-Jones, 2007, p. 12). ICALL has been regarded as particularly promising for grammar teaching because it can address specifically defined areas of knowledge. The effectiveness of an ICALL program depends, to a large extent, on its ability to recognize learners’ written input and to retrieve appropriate feedback. Typical ICALL programs are designed to tackle a specific grammatical point through explicit instruction, opportunities for practice with a focus on form and meaning, and immediate feedback on error awareness raising and correction.

Another major technological resource for teaching grammar is the corpus. Publicly available resources include the COBUILD Concordance Sampler, the British National Corpus, and corpora compiled by individual researchers, who can then load the data to existing concordancers such as MonoConc, AntConc, or Sketch Engine for learners to explore. The consensus is that corpora and concordancers can increase students’ exposure to authentic language data and thus enhance language learning, although the approach has been open to negative reactions because of the amount of work required by the learners.

The role of computer technology in providing learners with opportunities to interact and thus learn grammar in a much more implicit way has also been examined. Researchers have identified three main types of computer-mediated communication (CMC) as having potential for facilitating grammar teaching and learning. These will be addressed below.

Text-based synchronous CMC (SCMC), for example, has shown promise for developing grammatical competence because it offers opportunities for meaning negotiation and helps

learners notice language form. Specifically, SCMC has been shown to encourage learners to use a wider range of lexical choices, more formal and complex sentence structures, and a broader variety of discourse markers. Although it has been a concern that online discourse is characterized by off-task discussions and inaccurate language use, the adverse effects on language accuracy may be a result of a combination of the types of tasks carried out in SCMC, the complex interaction between complexity and accuracy in second language (L2) development, and the speculation that learners might have perceived SCMC as mostly an informal medium.

The role of asynchronous CMC, such as forums or discussion boards where learners can initiate or post in response to a message, has also been examined, with the main controversy being whether the time delay between interactions provides learners adequate time to reflect upon language form or inhibits them from seeking assistance on linguistic issues because of a lack of immediate feedback. Inaccurate language use has also been evident in asynchronous CMC, although it is more complex and formal than that found in SCMC.

A third way of using technology as mediating channels is telecollaboration, which usually refers to projects involving e-mail exchanges and synchronous text-based chat. The main advantage of e-mail is that it gives more time for learners to reflect upon and compose a message and thus encourages a focus on form.

As with the face-to-face contexts discussed earlier, corrective feedback within online approaches, which are primarily done through writing, has been researched as an issue in grammar teaching. Several studies have suggested that although the mode and delivery may have shifted from the oral, face-to-face classroom to written, online chats or e-mail, the issues of uptake and understanding using corrective feedback (explicit or implicit) have remained.

This entry has examined historically the role of grammar in language teaching. There is ample evidence of a pendulum swing between teaching grammar explicitly/deductively and providing the tasks and activities that encourage students to learn grammar inductively. Moreover, even when the times have favored more inductive approaches, a focus on grammar has persisted through the types of feedback offered and available, whether explicit or implicit, as evidenced by the research carried out on such activity. Similar issues and questions about the best approach to use for teaching grammar have persisted throughout the years. Ideas of how best to develop learners' grammatical competence have indeed pervaded language teaching and will likely continue to be a central concern for research and pedagogy.

Grammar in Political Debate

ANITA FETZER

Introduction

Applied linguistics examines the use of language in various contexts. One of them is political debate, referring to communicative exchanges between professional politicians in parliament and other institutional settings, between representatives of the media and politicians, and between politicians and the public. Political debate may also refer to the abstract field of political discourse, comprising political interviews and speeches, and political discourse in printed and electronic media.

The analysis of political debate considers the evasive use of language, metaphor and political equivocation, for instance. The results are not only of relevance to the scientific community but also find practical application by politicians, political advisors and speech-writers, and journalists and media personnel.

In the following the relationship between grammar and political debate is investigated, contextualizing the concepts of grammar and political debate, discussing political debate in the media, and illustrating some of the most pervasive communicative strategies.

Grammar

The meaning of the word “grammar” is rather complex. It may be used to refer to the system by which words and morphemes are organized into larger units, or it may be used to refer to a particular description of such a system in a codified text (a reference grammar), or even to the branch of linguistics dealing with such descriptions.

In ordinary language, grammar tends to be conceived as synonymous with prescriptive grammar, instructing language users how to build sentences in accordance with language-specific rules. The rules generally stem from the fields of syntax, especially word order and subject–verb agreement, and morphology, in particular inflectional morphology. From that perspective, grammar represents a normative system. Prescriptive grammar informs interlocutors whether a sentence is built in accordance with the codified rules of grammar and therefore counts as a grammatical sentence or whether it deviates from the rules and needs to be corrected. Because of its normative design, the rules of prescriptive grammar are considered to obtain in almost any communicative setting, irrespective of whether a sentence is used in formal or informal contexts.

In linguistics and language studies, “grammar” refers to a descriptive type of grammar containing all the necessary and sufficient rules which are required to build a grammatically correct sentence. Descriptive grammar is concerned with the “rules by which words change their forms and are combined into sentences” and with “the study or use of these rules” (Longman, 2007, p. 763). The latter entails both a linguistic-competence anchored system of rules and a performance-based use of rules in context. In a more specific reading, grammar is defined as “(1) the systematic study and description of a language, a group of languages, or language in general in terms of either syntax and morphology alone or these together with aspects of phonology, orthography, semantics, pragmatics, and word formation” (McArthur, 1992, p. 446).

The minimal unit of investigation in descriptive grammar is the clause and its constituents. More recently, the frame has been extended to cover the domain of discourse, analyzing the necessary and sufficient conditions which assign a stretch of text the status of well-formed discourse. Discourse grammar accounts for information structure, thematic structure, sequential organization and discourse connectives, to name but the most prominent ones. It may also accommodate constraints for the differences between spoken and written language, and between formal and informal context. The difference between spoken and written language is of particular importance for descriptive and functional grammars: Syntactically speaking, clauses tend to be less complex in spoken language. Semantically speaking, spoken language favors less abstract terms, and, pragmatically speaking, it displays a higher frequency of personal pronouns and other deictic expressions (see Biber, Johansson, Leech, Conrad, & Finegan, 1999).

Grammar is an extremely complex system and that is why it is almost impossible to cover the analysis of all its constitutive systems in an appropriate manner. Against this background, grammar tends to concentrate either on form or on meaning and function. Consequently, there are syntax-based grammars examining the structure of the language (e.g., Haegeman & Guéron, 1999), syntax-based grammars focusing on structure and on aspects of register and style (e.g., Greenbaum & Quirk, 1990; Biber et al., 1999), semantics-based grammars analyzing the question of how meaning is coded in linguistic structure (e.g., Dixon, 1991), and functional grammars investigating the question of how language functions with respect to the linguistic representation and construal of social reality (e.g., Givón, 1993; Halliday, 1994). While syntax-based grammars tend to conceptualize grammar as an autonomous system, which is relatively independent from society and culture, semantics-based grammars and functional grammars examine the connectedness between linguistic structure, linguistic meaning, and context, as is reflected in critical discourse analysis (Fairclough, 1995; van Dijk, 1998). In the latter paradigms, the intentionality of communicative action and the context- and genre-dependent instantiation of rules and constraints are considered explicitly. This is also the case in communicative grammar, in which grammar and strategic interaction are investigated (Leech & Svartvik, 1994).

Political debate is connected intrinsically with society and culture, and hence with meaning and function. Consequently, its analysis needs to be informed by a sort of functional grammar which may account for (a) communication and strategic interaction, and (b) the linguistic representation of social reality, for instance Hallidayan linguistics (Simon-Vandenbergen, 2000).

Political Debate

Analogously to grammar, politics is conceptualized differently in the field of political science and in ordinary language. On a more general level, politics refers to “ideas and activities relating to gaining and using power in a country, city etc.”, and on a more specific level it refers to someone’s “political beliefs and opinions” (Longman, 2007, p. 1266). Furthermore, it may denote the “activities of people who are concerned with gaining personal advantage within a group, organisation etc.” (p. 1266). In political science, research on politics entails research on political parties, political power, power structures, struggle for power, participation in power, and power and representation. It is also concerned with political systems, forms and structure of government, and political philosophy.

Politics is a multifaceted concept, which operates on the macro level of society as regards the art and science of government concerned with guiding or influencing governmental policy, winning and holding control over a government, political actions and practices, or policies. In the domain of party politics, politics refers to the management of a political

party, to the conduct and contests of parties with reference to political measures or the administration of public affairs, or to the advancement of candidates to office. In that sense, politics entails the total complex of relations between people living in society. On the micro level, politics is seen as “doing politics” in everyday life, concentrating on political agents and their political practices, for instance participating in political decision-making processes, communicating political decisions to the general public, or negotiating between competing interest groups.

Both macro and micro politics require language as a means of communication in order to exercise governmental control and to communicate felicitously in the political arena. Similarly to rules in grammar, which specify what counts as grammatical, well-formed, and appropriate, there are rules in the domain of politics, which specify what counts as political action, to employ speech-act-theoretic terminology (Searle, 1969), and which specify how politics *is done*, to employ a term from the field of ethnomethodology (Garfinkel, 1994). For instance, considering the possibility of having a house built may count as a private-domain anchored personal decision if two (or more) individuals intend to build that house for their own purposes. If the house in question was to be an official building, for instance a prison, school, or kindergarten, the decision to have the house built would count as a political decision, which would need to undergo institutional decision-making procedures.

The context-dependent nature of communicative action has consequences for political discourse, which is not only concerned with institutionalized politics but also with political processes, such as political discussion and decision-making processes. In mass-media-based societies, political discourse is primarily presented in the media.

Political Discourse in the Media

Political discourse in the media is a complex phenomenon: It is institutional discourse, media discourse, and mediated political discourse. As institutional discourse, it differs from everyday conversation in being subject to institutional constraints. As media discourse it is different from other types of institutional discourse by being, above all, public discourse addressed to a mass-media audience. As mediated political discourse, it is the outcome of the encounter of two different institutional discourses – those of politics and of the media.

The traditional concept of politics is anchored to the public domain of society but also interfaces with micro domains. It enters the private spheres of life through media and, in mediatized mass democracies, this is for most people the only way in which they ever encounter politics.

Political debate is performed orally using the grammar of spoken language: It displays features of interactiveness and involvedness, as is reflected in the strategic use of pragmatic markers, presupposition, and epistemic modality, and the use of various forms of regional dialect, which is referred to as conversationalization in critical discourse analysis (Fairclough, 1995; Fetzer, 2008). Political debate is also performed in the written mode using the grammar of written language. Naturally, political debate uses other relevant semiotic codes in a strategic manner, such as nonverbal communication, typography, music, and party-political logos and emblems. The interplay of the different semiotic codes allows political agents and media personnel to communicate their goals felicitously, appropriately, and persuasively (see Fairclough, 1998; Fetzer, 2006; Lauerbach & Fetzer, 2007).

Political debate uses various discourse genres, such as statement and speech in the contexts of election campaign, summit meeting, business meeting, or party conference; interview in the contexts of TV or printed media; multiparty discourse in the context of panel interview and parliamentary debate; and report, analysis, commentary, editorials,

or letters to the editor. All the discourse genres are employed strategically to “talk politics” and to talk about politics, persuading the general public or particularized subgroups to support a politician and their party or government. Moreover, the discourse genres do not occur in a void but are embedded in journalistic news discourse and may be repeated as sound bites in later programming (Lauerbach, 2004). Ordinary people may also join in mediatized political discourse in audience-participation programmes, such as panel interviews, standing in for the interviewer and asking questions, or through members of the home audience calling in or sending e-mails.

From a pragmatic angle, political discourse in the media can be conceived as communicative action (Fetzer & Weizman, 2006). As in all types of persuasive discourse, the differentiation between perlocutionary act (Austin, 1980) and perlocutionary effect (Searle, 1969) deserves particular attention. The relevance of the distinction between intention and effect is highlighted by Chilton and Schäffner, who state that the perlocutionary effect “is . . . of crucial importance in political discourse analysis in particular, because it points to the potential discrepancy between intended effect (that is, effect that some hearers may infer to be intended) and the actual effect on the hearer” (2002, p. 11).

The following sections present selected topics in political discourse analysis, demonstrating the context-dependent use of grammar and the intended perlocutionary effects.

Personal Pronouns in Political Debate

Personal pronouns are an important means of referring to communication partners while at the same time signifying the nature of their interpersonal relationship as regards power and solidarity (Mühlhäusler & Harré, 1990). Pronouns are not just a very economic way of expressing reference – they are also of immense importance in how we interpret and signify the world around us. This is particularly relevant to the context of political debate in which political agents present themselves, their allies, and opponents in and through the media.

In political debate, political agents and media personnel frequently do not only speak on behalf of themselves but rather represent a collective voice, such as a political party or the government of a media institution. They may speak for themselves as individual political agents or they may speak on behalf of a collective political agency. Self-references may thus entail both singular reference and collective reference, and may express singular and collective agency. By saying “*we’re* putting a large amount of money into public services, into schools, into hospitals, law and order” the British prime minister refers to both himself and his government, while in “*we* did change *our* position on it”, he makes use of *inclusive we*, referring to a group including speaker, hearer, and some other people. In political debate, the latter tends to express solidarity. *Exclusive we* refers to a group of people including the speaker but excluding the hearer, expressing power. *We* may also express the widely accepted *pluralis maiestatis*.

There are other examples of multiple reference. The English pronoun *you* can refer to the addressee in the singular and in the plural, and it can be used to express generic reference, meaning “somebody” or “one”, including the speaker. In political debate it can refer to an unspecific, indeterminate group, such as a political party, as in “the point *I* was making is *you* won’t solve the problem by saying the Conservatives want to sound tough.” Here *you* does not refer to an actual individual but rather to the individual as a representative of that group. The referential domain of *you* is so elastic that it can even embrace the whole of humanity (Wilson, 1990).

To add a further level of complexity, the meaning of personal pronouns can shift as the status of the participants shifts in interaction. This may occur in terms of social roles (e.g.,

a politician may speak in her or his social role as prime minister and in her or his social role as spouse or parent) and in terms of roles in talk (e.g., members of the audience may take on the role of interviewer) and footing (e.g., the participant may speak as author or as principal; Bull & Fetzer, 2006).

The strategic use of pronouns is of particular relevance to the investigation of political debate, which has become an instance of media communication and mass speaking (Fairclough, 1995). In that particular context, alignment and solidarity is expressed through the strategic use of language. Here, the group indexical *we* is considered to be a major factor in mass speaking. Because of an individual's multiple social, discursive, and interactional roles, a personal pronoun can refer to more than one identity and therefore can express multiple meanings. For instance, the pronoun *we* might refer to the dyadic set of politician and interviewer, but the set might also include the audience in the studio, the audience at home, the party the politician represents, or the government of which he or she might be a member. Given their not always clear-cut domains of reference and the possible multiple meanings expressed, it is not surprising that political agents use personal pronouns to good effect, for example to accept, deny, or distance themselves from responsibility for political action; to encourage solidarity; to designate and identify both supporters and enemies.

Discourse is an important instrument in exercising political power and control. In political debate interlocutors present their own identities and the identities of others by using personal pronouns in a strategic manner, expressing inclusion and exclusion, and power and solidarity.

Transitivity: Agents and Non-Agents in Political Debate

Another means of exercising political power and control is managing the way in which social agents are represented in discourse: They can be presented as agents (i.e., as intentional beings who are in control of their actions) and they can be represented as passive agents (i.e., as powerless agents on whom actions are performed and who are thus not in control of what they do). An important grammatical device is to represent active agents as "doers" in their congruent realization as grammatical subject, logical subject, and psychological subject, and to represent non-active agents ("non-doers") in the semantic role of patient (Halliday, 1994). For instance, in the clause "the prime minister has announced drastic cuts," "the prime minister" is grammatical subject, logical subject, and psychological subject. The clause "drastic cuts have been announced" contains the grammatical subject "drastic cuts," which is also psychological subject but not logical subject. Here, the intentional agent, who announced the cuts, is not represented overtly and needs to be inferred from context.

In discourse, agents may not be represented at all and thus may be excluded from the discourse altogether. This may be achieved by the use of nominalizations and other types of grammatical metaphor. Exclusion of agents may be done consistently throughout the discourse, but there may also be temporary suppression or backgrounding. Other relevant means of representation are genericization, for instance "politicians have lost touch with reality," and specification, which is usually realized in parataxis, as in "politicians, bureaucrats, and ecologists." Furthermore, there is indetermination, when social actors are represented as anonymous individuals (e.g., as "people") and differentiation, when their identity is made explicit (e.g., "Mr Smith, leader of the community centre"). Generally, there tends to be a close connection between the social roles that agents are given and their grammatical roles in discourse (van Leeuwen, 1996).

Metaphors in Political Debate

Metaphors are seen as an important device for representing social reality from a different angle, thus contributing to a richer concept while at the same time distorting what is considered to be external, objective reality. In cognitive semantics, metaphor is not only assigned the status of a temporary distortion but seen as a fundamental device for classifying external reality. Thus, metaphors are at the heart of rhetoric, (social) stylistics, and cognitive linguistics (Chilton, 2004; Musolff, 2004). Political worldviews are categorized along the lines of moral conceptual systems, for instance as strict father morality or as nurturant parent morality (Lakoff, 2002).

Metaphors are seen as a fundamental device for categorizing and classifying the external world, and it is their classifying force that makes them an indispensable means in political debate.

Concluding Remarks

In our mass-mediatized world, politics is conducted in and through the media. To communicate felicitously and persuasively, political debaters need to use the grammatical repertoire of language in both a context-dependent and a strategic manner. Only then may they succeed in getting across their ideas, policies, opinions, and criticism.

By using personal pronouns, cognitive metaphors, or active and passive voice, political debaters may foreground a particular piece of information, thus highlighting its relevance. They may, however, also background some piece of information, hedging its importance in order to remain indirect, evasive, or diplomatically unclear, and by selecting the appropriate genre for their communicative intent (e.g., Twitter, interview, or talk show) political debaters may present themselves as committed, emotive, and powerful political agents.

Grammar in the Law

JAN CHOVANEC

Legal language is seen as a specialized register, that is, a functionally differentiated variety of language used in certain professional contexts. As such, it can be described in terms of its conventional lexicogrammatical features. Yet, it is difficult to generalize its salient linguistic characteristics because the concept of “legal language” covers a very broad range of different, though related, legal discourses. The written language of legal documents may perhaps be seen as the most representative form, possibly followed by written or spoken judicial decisions that make up case law. Significantly, however, there are other genres, such as the spoken discourses of courtroom interaction, legal consultation, and police interrogation. In all these contexts language is used in characteristic ways, and the typical lexicogrammatical features of one discourse type will not necessarily overlap with those of another. Nevertheless, despite this degree of contextual diversity, these particular legal discourses will be described here with respect to their typical grammatical features—features that may contribute to the general perception of “legal language” as complex and unintelligible. This description will be followed by an account of the trend toward the simplification of legal language at the level of syntax, which has, over the past few decades, increasingly affected the ways in which legal documents have been drafted. Grammar, however, has yet another role in the law: it can be the actual bone of contention in disputes over the interpretation of complex legal language and, importantly, also as forensic evidence. In the latter case, linguists are called upon to analyze textual evidence and seek any departures from expected norms—at the grammatical and other levels—in an effort to establish idiosyncratic styles and identify the authors of disputed texts.

Grammar in Written Legal Discourses

The language of the law has traditionally been described as having a tendency to be “wordy,” “unclear,” “pompous,” and “dull” (Melinkoff, 1963, p. 24). Indeed, the “convoluted” syntax of written legal texts is among the characteristic markers of this register: it plays an almost ritual role in identifying it (see Coulthard & Johnson, 2007, p. 37). The addressees of legal texts are not only those who are bound by them (legal subjects) but also legal professionals, such as judges, who may be called upon to interpret a given text with respect to the intertextual framework of other legal texts.

Written legal texts depart from everyday language in various respects. Owing to the different circumstances under which they are produced and received, legal texts should not be viewed through the prisms of discourse norms of other genres (be they spoken or written). Legal drafters write highly formulaic, noncreative texts that are impersonal and devoid of any originality, often with entire sections directly copied from other documents or form books. After careful planning, they remove any linguistic redundancies that are so typical of everyday language and that generally help to make a text easier to process. On the receiving end, written legal texts are not assumed to be understood after a single reading—either by lay readers or legal professionals. Some texts, such as legislation, are to be engaged with repeatedly, that is, reread, scrutinized, and eventually interpreted. The process of interpretation of legislative rules—which are purposely general and all-inclusive

—consists in their application to the details of a particular case. This means engaging in the highly contextualized practice of identifying similarities and differences between a given situation and legal rules, that is, finding whether the particular details are in harmony with or in violation of the law.

Although specialized registers typically do not have distinct grammars (Gibbons, 2003, p. 55), the grammar of legal language—especially that found in operative documents—does differ in many respects from everyday language. There is a marked preference for impersonal constructions, passives with deleted agents, nominalizations, and complex nominal phrases. Other salient grammatical phenomena include specific cohesive means, modal verbs, sentence complexity, grammatical coordination (between clausal, adverbial, nominal, and other elements), nominalized expressions (with the necessary implication of a high degree of lexical density), logical structure, and syntactic discontinuities.

Cohesion

In general, written legal texts such as legislation and contracts prefer extreme explicitness. For the sake of precision and unambiguity, pronominalization tends to be avoided, as is the use of synonyms (except in coordinated binominals). While the former might create ambiguities, the latter might imply non-equivalence and hence the existence of two (or more) independent concepts. Instead, legal texts will reuse the same lexical item because such consistency meets the requirement for accuracy of legal language. Cohesion is thus marked by the preference for one particular means of lexical cohesion, namely repetition, at the expense of pronominalization and substitution. In non-legal contexts, a similar degree of lexical repetition would be seen as excessive and redundant. In fact, it is precisely the over-explicit repetitiveness that may contribute to the stereotypical perception of legal texts as unnatural and “wordy.” Clearly, this indicates that legal texts are wrongly judged when evaluated by the discourse norms of other genres.

Yet legal texts in English rely heavily on another system of achieving cohesion: the use of complex adverbs of the *herein*-type, which are rarely found in other registers or in everyday language. These adverbs are composed of two elements, whose meaning is compositional: the pronoun *here* or *there* and one or two relevant prepositions. The order of these elements is opposite to the corresponding prepositional phrases: for example *herewith* = with this document, *thereinbefore* = coming earlier in that document. While adverbs with *here*- refer endophorically to the actual text (or a particular segment of the text) in which they are used, adverbs with *there*- refer exophorically to other texts, illustrating the intertextuality of written legal discourses.

Although these complex adverbs may occasionally lead to notorious ambiguities in interpretation (e.g., *hereunder*—under this document, or under this section of the document?), they are, all in all, a very efficient means of constructing cohesion and achieving crossreferencing in legal texts. By allowing for condensation at the phrasal level, they enable the drafter to omit information that is, in most cases, irrelevant or obvious. As a result, the information load (and the lexical density) of the sentence is reduced.

Thanks to their universality, such adverbs also enhance the formulaic character of legal texts in which the equivalent prepositional phrases would have to be much more specific and tied to the local verbal context. In other words, these complex adverbs make it possible for the author to avoid the specification of details whenever the texts need to refer to themselves or their parts: thus, for instance, *the parties hereto* comes to substitute the open set of alternatives such as “the parties to this agreement/contract/addendum/convention/treaty/,” and so on, while *hereunder* succinctly replaces the more specific “under this document/deed/contract/section/paragraph/article/,” and so on. In this sense, such formulaic complex adverbs help legal professionals—who habitually deal with such texts—to produce and process legal texts in a more automatic and condensed manner.

Modality

In legislation and contracts, the modal verb *shall* is used with a “mandatory” force, that is, to impose obligations (while *must* and *have to*—which are common in conversation—tend to be avoided: see Trosborg, 1995). The mandatory meaning is also conveyed through the present tense, especially in performative utterances representing the “constitutive” nature of law (grants of rights, assumptions of obligations, etc.). Less frequently, *shall* also appears in future references and in predictions. Other modals have similarly dual functions: *may* (as well as *can*) expresses permission and possibility, sometimes leading to ambiguities and requiring legal interpretation over whether the deontic or the epistemic meaning was intended. The putative *should* is frequent in conditionals to express a theoretical possibility.

The Sentence and Grammatical Transformations

Legal documents follow the rules of written grammar and are probably the most removed from the syntax of spoken conversation. One legal sentence typically consists of many clauses which would be formulated as a sequence of independent sentences in non-legal contexts. Sentences are usually very long; in the past, a whole document could even be constructed from a single, unpunctuated sentence. (One reason for this practice was the attempt to prevent any subsequent insertions of punctuation marks which could alter the meaning of the original manuscript.)

Clauses in legal texts are linked in two distinct ways: paratactically and hypotactically, with nonfinite clauses being particularly frequent. While *parataxis* leads to the cumulative linking of clauses that could easily stand on their own in other genres, *hypotaxis* concerns the subordination of clauses and clausal elements, often with several levels of embedding. Such coordination and subordination of finite and nonfinite clausal elements adds not only to the notorious length of legal sentences but also to their syntactic complexity. As a result of the elaborate syntax—combined with high lexical density—legal texts may turn out to be difficult to understand, especially by the lay public.

As with other genres of official and impersonal communication, legal language often uses *verbo-nominal predication*. This means that a clause contains a semantically vague verb resembling a copula and acting as little more than a mere carrier of the grammatical categories. The semantic core of the predication, by contrast, is shifted to the nominal element (e.g., *to provide* → *to make provisions about*). Conceptually, verbo-nominals recategorize processes into products (that is, turning intangible but dynamic “happenings” into concrete but static “things”). As a result, they become comparatively more open to quantification as well as to clausal and adverbial qualification (see below).

Legal texts frequently use the *passive voice*. This diminishes the role of the semantic agent, who either is expressed through an optional sentence constituent (that is, a prepositional phrase with *by*), or, more frequently, disappears from the clause entirely. Unexpressed agents of passives and past participles make legal texts not only more impersonal (thus contributing to the “objectification” of the content), but also more general and universal (e.g., passives such as *it is deemed*, *it is understood*, *it is to be interpreted as*, etc., which leave the agency open to an unspecified doer). In addition, the passive has a significant textual function, especially in languages with a relatively fixed word order, such as English. By allowing sentence constituents to be rearranged within a clause, the passive helps to satisfy the principles of end-weight and especially end-focus. As a result, sentence structure can more adequately reflect the natural progression from known to new information, thus meeting the requirements of functional sentence perspective (theme–rheme, topic–focus articulation).

Present and past participles are used frequently as adjectival modifiers. As nonfinite clausal elements, they significantly condense the syntactic structure of the sentence. In this way,

they pack more information into the clause, making the texts not only grammatically more complex but also cognitively more difficult to unravel. The same holds for some *adjectives* (e.g., an offence punishable under section 182) and *nominalizations*, which have a similar clause-condensing function (e.g., *permission*; *termination*; *compensation*). These nominal transformations actually represent underlying processes and can be potentially expanded into their full clausal equivalents. It is in such finite clauses that, to use Halliday's terms, these "grammatical metaphors" find their congruent (that is, primary) realizations. Further complexities arise from the morphological structure of some grammatical metaphors (e.g., *unimpeachable*) and their combinations into extended groups (e.g., *review of arrangements for judicial appointments and removals*; Northern Ireland Act, 2009).

Syntax of Legislative Writing (Legislative Writing and Syntactic Discontinuities)

The grammar of legislative writing reflects the cognitive structuring of its content in terms of the underlying legal norms: concrete sentences, with their grammatical and syntactic structures, are mapped onto the abstract provisions. Legislative texts must meet the requirements of precision and unambiguity, yet they must also allow for all-inclusiveness and discretion in the actual decision-making practice. The syntactic structure of legislative provisions is built on the structure of the directive "rule of law," which has been described by the legal theorist Hans Kelsen (2006 [1949], p. 45) as "*If A, B ought to be.*" This is known as the *legal norm*, which has a mandative and normative character (unlike the "law of nature," which relies on the causative relation of "*If A, then B*"). It is used for imposing obligations and conferring rights (cf. the older views of law as "the binding command" or "the legislator's will").

At the syntactic level, the legal norm comes to be realized through *conditional sentences*, introduced with conjunctions such as *if*; *where*; *provided that*; *unless*; *in the event of*; and *in case of*. Conditionals typically follow one of two abstract patterns: "*If X, then Y shall do Z*" and "*If X, then Y shall be Z*" (Crystal & Davy, 1969; Bhatia, 1994). The legislative provision then consists of three elements: participants, processes, and circumstances. In legal theory, these are known as the legal subject (Y), that is, the party subject to the provision; the legal action (Z), that is, the actual right, obligation, or prohibition imparted through the law; and the case description (X), that is, the circumstances that need to be present for the application of the main provisionary clause consisting of the legal subject (Y) and the legal action (Z). Occasionally, other structures may convey the conditional meaning as well, for example relative clauses and various post-nominal specifications, as in the following sentence: *A person desiring to appeal against such decision as is mentioned in subsection (2) shall give a written notice to the Authority specifying the decision against which he wishes to appeal and the grounds upon which such appeal is made*; Broads Authority Act, 2009.

Legislative provisions thus follow a *two-part interactive cognitive structure*: the main provisionary clause is interrupted at various syntactic openings by numerous qualifications (preparatory, operational, and referential), which are "meant to answer legal questions and doubts, and offer clarifications about various aspects of the main provision" (Bhatia, 1994, p. 152). The two moves (that is, the provisionary clause and qualifications) interact and result in making the provision—and the legal norm—precise and unambiguous. Thanks to this, the syntax of legislative provisions closely follows the process of legal reasoning. The actual processing of legislative writing then consists of the extraction of the main provisionary clause (that is, the legal action that is to apply to the legal subject), which is embedded in numerous specifications, limitations, and intertextual references. The qualifications then modify the main provision by significantly limiting the scope of its applicability.

The interaction between the provisional clause and the attendant qualifications disrupts the unimpeded syntactic progression of the sentence because the qualifications are inserted at any available place whenever the need arises to specify the nature of the legal action. This results in unexpected *syntactic discontinuities*, which are characteristic also of other kinds of written legal language. Individual elements within a sentence are immediately qualified by means of phrasal or clausal insertions, sometimes even across phrase boundaries and at the expense of expected patterns of word order. The insertions may be very extensive and themselves subject to further qualifications, giving rise to several levels of embedding (e.g., *The Secretary of State may by order made by statutory instrument make transitory or transitional provision or savings in connection with the coming into force of any provision of this Act*; Northern Ireland Act, 2009). As a result of syntactic discontinuities, a legal text may appear awkward (hence the frequent accusations of legal style as “tortuous”), though it becomes very effective in conveying the intended meaning. Syntactic discontinuities illustrate that in legal language, style is subordinate to precision and unambiguity. These goals are pursued even at the expense of readability, for the lay person or legal professionals alike.

At the same time, however, precision in legislative instruments is balanced with *flexibility* and all-inclusiveness. Over-explicit lists and enumerations tend not to be provided. Instead, flexibility is achieved primarily lexically through such subjective terms as *reasonable*, *relevant*, and so on, which are to be interpreted against the specific circumstances of a case. These lexical items allow for discretion in judicial decision-making (see Maley, 1994, p. 27).

Grammar in Spoken Legal Discourses

The spoken language of law takes on a variety of different forms. It includes police interviews, courtroom interrogation, expert witness testimony, lawyer–client interviews, jury deliberation, and other genres (see Cotterill, 2003; Heydon, 2005, etc.). The lexicogrammatical complexity and textual patterning of legal–lay and legal–legal discourses may also reflect different modes of habitual reasoning (e.g., narrative vs. paradigmatic, see Heffer, 2005). When allowed to use the narrative style, the litigants may, for instance, use passives and impersonal constructions, thereby eliminating semantic agents. In this way, they may inadvertently render their accounts inadequate for legal purposes (Conley & O’Barr, 1990).

Courtroom interaction is shaped by particular contextual and power relations that have an impact on not only the discourse structure of the speech event (in terms of sequencing, turn taking, etc.) but also its microlevel grammatical realization. In different stages of a trial, there is a tendency to use different grammatical constructions. This preference is directly tied to the ultimate aims of the interactants, that is, the co-construction of one’s own account and the destruction of the opposing party’s story. Thus *direct examination* (known as “examination in chief” in British English), marked by a cooperative and supportive mode, tends to include a higher proportion of open-ended questions, allowing for answers that are more narrative.

By contrast, questions in *cross-examination*, marked by a combative and adversarial mode, tend to be asked differently: as yes/no questions and, significantly, narrative statements with question tags. The tags are either grammatical or lexical, sometimes appended as separate questions (e.g., *Correct?* or *Is that right?*). As information-seeking questions occur less frequently, responses are often limited to mere yes/no confirmations.

Grammatical forms used to ask questions may be arranged on scales reflecting increases in coerciveness, information control, information deniability, and so on (Gibbons, 2003). For instance, some syntactic transformations, such as nominalizations and statements

projected in reported speech, may be difficult to deny because they present the crucial proposition in the form of an embedded presupposition that is taken for granted. Various jurisdictions place restrictions on the admissibility of leading and captious questions that suggest the desired answer or contain unproven suppositions (e.g., *I suggest . . . ; I put it to you that . . . ; Is it not the case that . . . ?*).

Questions asked during dialogic courtroom interrogation employ frequent *repetition* and *structural parallelism*, often for rhetorical and strategic purposes and with the aim of influencing the jury. Similar phenomena appear in the lawyers' opening and closing speeches, which are preplanned and nonspontaneous speech events of the "written-to-be-spoken" type. Such monologues contain interactive phenomena (means of direct address, questions, commands) addressed to the jury as the actual and explicitly ratified recipients of messages in the complex multi-party participation framework of courtroom discourse.

Some *discourse markers* are used in specific ways. Lawyers, for instance, often preface their utterances with the "so" summarizer in order to emphasize the previous sequence and draw logical inferences. Since the questioners' inferences come in the form of yes/no questions, they are difficult to contradict (Johnson, 2002; Cotterill, 2003). Courtroom interrogation also includes other phenomena typical of spoken language, such as hesitation, false starts, and reformulations. These occur especially when defendants and witnesses who, subjected to face-threatening acts, are forced to provide unrehearsed and dispreferred responses, are made to concede some facts detrimental to their case, and are found to have lapses of memory about past events.

Communication in the courtroom follows *conversational norms* different from the usual norms of authentic conversation; the operation of some pragmatic principles and maxims is modified or suspended. Silence, that is, the non-production of any verbal response, assumes various meanings, ranging from a lack of knowledge to an admission of guilt (see Kurzon, 1995).

The Simplification of Legal Grammar

Legal language has been negatively commented on for centuries. Some of its early critics included the English king Edward VI (1547–53), the British satirist Jonathan Swift, and the US president Thomas Jefferson, among others (see Asprey, 2003). The English language probably attained the height of its verbosity in the 18th century (Melinkoff, 1963), not only in law but also in other domains, such as literature. Criticism has been levied against both vocabulary (archaisms, binominals, complex prepositions, French and Latin expressions) and grammar (complicated syntax, passives, impersonal constructions, formulaic phrases). The negative public attitude has become lexicalized into commonly used pejorative labels referring to legal language, such as legalese, gobbledygook, and legal jargon.

The complexity of legal language is sometimes explained in terms of *privileged access*. It is argued that lawyers use complicated language as a means of intentionally and willfully mystifying their activities, that is, in order to preserve their professional exclusivity and to prevent the public from understanding their discourse. However, many legal genres—such as contracts—face the "two-audience dilemma": they are produced by lawyers for non-lawyers, yet are ultimately interpreted by other legal professionals (Gibbons, 2003).

Criticism of legal language is sometimes misguided, conflating two separate issues: "legal style" and "bad style." Some of the calls for plain language are directed less against particular registers, such as legislation and contract law, than against the overcomplex style that is often found in official and institutional contexts. Simplification for the sake of clarity has traditionally been promoted in various style manuals, which have enjoyed wide

popularity for over a century (see such classics as H. W. Fowler's *The King's English*, 1906, E. Gowers's *The Complete Plain Words*, 1954, and George Orwell's critical essay *Politics and the English Language*, 1946).

Systematic attempts to simplify legal language date from the 1970s. Several US banking and insurance institutions started rewriting some of their legal documents for the public, motivated partly by a desire to increase their market share and partly by the need to follow new consumer legislation requiring "plain language." Legislative drafting in the US is now also guided by explicit instructions on plain language style. Other, mostly English-speaking, countries followed suit, introducing various grassroots initiatives calling for language reform and demanding that in democratic societies people, as the subjects of legal norms, have the "right to understand." Although the grounds for language simplification have been repeatedly questioned by linguists, who have provided functional explanations for the peculiarities of legal language, the trend toward simplification seems to have the support of the general population.

More recently, many public and government institutions have successfully rewritten their documents for the public, assisted by the recommendations or the commercial editing services of plain-language groups. Typically, the rewriting removes impersonal constructions, extensive embedding, and long sentences, as well as the passive voice, which has been subject to prolonged criticism despite its well-defined grammatical functions.

Linguist-led simplification of legal language has also been successful. In the US, jury instructions in many jurisdictions have been rewritten to make them more intelligible, and significant progress has been achieved internationally with the comprehensibility of police cautions (called "Miranda warnings" in the US), which have also been simplified (see Cotterill, 2000; Gibbons, 2003). Some linguistic simplification, such as the replacement of some archaic vocabulary, has also resulted from recent judicial reform by Lord Woolf in the UK (1999).

Grammar as Linguistic Evidence

Over the past decade, the new discipline of forensic linguistics has drawn on various levels of linguistic analysis, including grammar, in order to provide evidence in legal cases. Lexical collocations and syntactic structures have been linked to the idiosyncratic use of language and treated as likely markers of personal identity, especially in cases of disputed authorship. Syntactic analysis has helped to reveal inconsistencies in the alleged use of language by individuals, for example in cases where evidence was doctored by the police. For instance, Coulthard (2002) showed in the 1998 retrial of the infamous 1950s UK case of Derek Bentley that what had been originally presented as a verbatim monologic witness statement—on the basis of which Bentley was executed—was in fact a multivoiced text. The all-too-frequent negative statements were found to be traces of dialogue, that is, answers to questions, while the position of the discourse marker *then* in the post-subject rather than the initial position was established as a typical feature of police language. Forensic linguistic evidence is also crucial in cases of textual borrowing, for example plagiarism.

Grammar of English as a Lingua Franca

BEYZA BJÖRKMAN

English today has reached global dimensions no other language has come near before. It is used in a very large number of domains and is spoken by millions of people for various purposes. English as a lingua franca (ELF), that is, as a vehicular language among speakers of different mother tongues, represents the largest use of English in the world today. In fact, those who speak English as a lingua franca greatly outnumber the native speakers in the world.

For anyone interested in language, and especially for those involved in applied linguistics, such a widespread use of a language constitutes a very exciting field. A natural first step is to investigate this language use and describe it. This entry has as its main aim to provide a brief description of grammar usage when English is used as a lingua franca, as well as bring to the fore some critical issues on the topic. First, the reasons for the need to describe English as a lingua franca will be discussed, followed by important studies and corpus work on the topic. Then a sample ELF setting will be examined, elaborating on grammar usage. Finally, some points of debate will be discussed with references to relevant literature and the sample ELF setting.

Why Describe English as a Lingua Franca?

Investigating ELF usage in a number of domains (e.g., engineering, business), settings (e.g., universities), and countries (e.g., European and other) is useful for four main reasons. It is important to raise awareness in this kind of use of English in today's world, where English is used mostly by its non-native speakers. First, those who use English as a lingua franca communicate predominantly with other non-native speakers. On this note, they do not need to consider cultural issues to the same extent as those who speak English to communicate with native speakers.

Second, ELF needs to be described for theoretical reasons (Mauranen, 2005, p. 273). Being a contact language, it deserves to be studied just like pidgins and creoles have been researched. Doing research within ELF is likely to reveal very interesting results since, like speakers of pidgins and creoles, ELF speakers come from extremely diverse backgrounds and the numbers of those who speak English as a lingua franca are constantly growing. These factors together make the situation even more complex (Mauranen, 2005, p. 273) and ELF even more deserving of being studied properly.

Third, different ELF settings should be studied for linguistic descriptions to be available. The use of English as a lingua franca is a different function of the language with a variety of adaptations of native forms. To allow for the testing of theoretical hypotheses and looking into areas where ELF usage is applicable, descriptions are necessary (Mauranen, 2005, p. 274). One certainly needs some anchoring in this respect. What was earlier available as a point of comparison was the native speaker norm and model. Because of the specific nature of ELF situations where speakers come from various backgrounds, the native speaker model is not an appropriate point of reference when evaluating communicative effectiveness (Mauranen, 2005, p. 274).

ELF research challenges the homogeneity of grammatical systems, speech communities, and competence. In today's largely heterogeneous world, we need heterogeneous language

models (Canagarajah, 2006, p. 211). The global English speech community where speakers come from a wide range of first language backgrounds is by no means homogeneous, which brings the reality that the language used cannot follow a homogeneous model. English today is used in this global community with varying degrees of competence, and the results of research within different ELF settings have shown us that speakers in ELF settings seem to achieve effectiveness despite the heterogeneity (Canagarajah, 2006, p. 211).

Finally, descriptions of ELF are necessary for possible applications of it. Those who need to operate in ELF settings along with decision-makers in ELF settings, for example, managers of international universities, need to gain a better understanding of it, to be able to determine what to pay attention to, what to avoid and what to prioritize. The large number of speakers who speak English as a lingua franca and settings legitimizes the need for research about the ELF phenomenon.

Studies on the Grammar of English as a Lingua Franca

Although research into ELF started relatively recently, the proliferation of investigations that have been carried out on different aspects of it has been dramatic. The increasing use of English as a lingua franca in a wide range of settings opens up possibilities for carrying out studies of varying nature. In any attempt of describing and analyzing language use, form, that is, grammar, plays a pivotal role, as meaning cannot be created without grammar.

The release of two important corpora, free for use by researchers, has already provided researchers with substantial data, resulting in studies on ELF grammar. A useful and important preliminary here, before moving on to a review of these studies, is a brief review of these corpora that provided data for large-scale investigations on form.

The Vienna–Oxford International Corpus of English (VOICE; www.univie.ac.at/voice) is a large spoken corpus project led by Seidlhofer with recordings of about one million words of mainly English produced by speakers of continental European languages from professional, educational, and informal settings (VOICE). Projects based on this corpus have provided valuable information on ELF settings, predominantly with reference to lexicogrammar. VOICE includes an estimated 1,250 ELF speakers with approximately 50 different first languages at the time of writing, and comprises a wide spectrum of speech events from different domains, functions, and participant roles. Another very important corpus project is the English as a Lingua Franca in Academic Contexts corpus (ELFA; www.eng.helsinki.fi/elfa) from Finland, being the largest work on ELF usage in academic settings. It supplies authentic data from naturally occurring speech events, representing crucially high-stakes academic events. ELFA contains one million words of transcribed speech of approximately 131 hours of recorded speech and has 650 speakers from 50 different first languages. Both these corpus projects have contributed considerably to our knowledge on the grammar of ELF.

To many, the list provided by Seidlhofer on some early observations constitutes the set of grammar commonalities of ELF usage (Seidlhofer, 2004). Among these observed commonalities are (Seidlhofer, 2004, p. 240):

- Dropping the third person -s (e.g., *He say*);
- The interchangeable use of the relative pronouns *which* and *who* (e.g., *The man which was here yesterday . . .*);
- The non-standard usage of articles in general;
- Invariable tag questions, for example, *isn't it? No?*;
- Redundant prepositions, for example, *study about*;
- High frequency of some verbs of "high semantic generality," for example, *do, have, make*;
- Using *that* clauses instead of infinitive clauses, for example, *I want that . . .*;
- Increased explicitness, for example, *black color*.

The existing studies on the grammar of ELF reveal considerable nonstandardness and divergence from standard norms. Some of the features that were proposed as commonalities above seem to find support from studies that are based on empirical data.

To begin with, in an investigation of the *third person -s* in group discussions, there were 29 cases of third person singular *-s* and 15 cases of superfluous *-s*. However, almost 80% of all cases followed standard norms in the corpus (Breiteneder, 2005). Another item in the list of commonalities is the invariable question tag, for example, *isn't it?* This item, along with some other nonstandard usage, is investigated in another study where the data are made up of four hours of naturally occurring exchange student talk (Hülmbauer, 2007). These studies arrive at similar conclusions: correctness and effectiveness do not go hand in hand, and such variations of usage in ELF situations are natural developments that are based on functional usage (Hülmbauer, 2007, p. 29).

Another interesting feature of grammar in ELF settings is the usage of the progressive aspect (i.e., *-ing*). Although it is not included in the list by Seidlhofer, it is reported to be common in ELF usage (Ranta, 2006; Björkman, 2008a, 2008b). Speakers in ELF situations often seem to opt for the *-ing* form instead of the simple form regardless of what the situation might require (Björkman, 2008a, 2008b). Support for this comes from a comparative work based on the ELFA and MICASE (The Michigan Corpus of Academic Spoken English), showing that the progressive form was used in a larger variety of contexts by speakers in ELF settings. However, it was actually used in a "standard-like" way in 87% of all the cases (Ranta, 2006, p. 111). Another study related to tense usage reported from a German university where students display a variation of tense and aspect usage (Erling, 2002). The reason, as suggested in the results, was not because the students lack that particular usage in their mother tongue, but because it simply was not essential for communication (Erling, 2002, p. 11). In a broader study carried out in the same setting, an examination of attitudes and motives of university students studying through the medium of English revealed a wide range of nonstandard features. The variation in the features investigated was dealt with similarly: nonstandard norms were accepted based on communicative effectiveness, which is then related to the phenomenon of new Europeanism where individuals use English in a "non-culturally restricted way." This new Europeanism brings with it the need to accept variation in forms based on comprehensibility instead of conforming to native speaker norms (Erling & Bartlett, 2006, p. 33).

In another analysis focusing on the use of English in international settings, an analysis of 22 hours of naturally occurring interactions reports grammatical choices that the speakers made (Meierkord, 2004). The results of this study indicated a surprising 9% only of divergent usage, that is, usage that did not conform to the standard norms of English. This study differs from the others mentioned here with its approach to the source of nonstandardness: the divergent usage was investigated in terms of first language backgrounds. The finding that is of highest relevance to this encyclopedia entry is the set of underlying patterns in usage that coincide with patterns in new Englishes, for example, patterns such as not marking plurality (Meierkord, 2004, p. 113). ELF is described as a heterogeneous language form that is heavily shaped by speakers' first language backgrounds. In addition, she claims transfer phenomena, developmental patterns, and nativized norms as well as simplification, leveling, and regularization strategies characterize ELF speech (Meierkord, 2004, p. 129).

The aforementioned studies on the grammar of ELF reveal considerable nonstandardness and divergence from standard norms but also communicative effectiveness despite the nonstandardness. At first glance, the nonstandardness may, rather simplistically, be taken as simply erroneous non-native speaker production. For a better understanding of the issue, however, one needs to search beyond the surface forms and look at underlying patterns of nonstandardness, for example, reducing redundancy or creating extra explicitness, at a finer level of linguistic detail.

Grammatical Commonalities and Underlying Patterns in an ELF Setting

An example ELF setting comes from Sweden, where English is increasingly being used as the medium of instruction in higher education, especially in engineering, natural sciences, and medicine. Large numbers of exchange students, foreign scholars, and Swedish lecturers and students all face a variety of tasks that they need to complete through the medium of English on a daily basis.

The data from this example setting, totaling up to 69 hours of recordings (27 hours of classroom group-work, 42 hours of lectures), reveal interesting facts about ELF grammar. In order not to allow for incidentalism, that is, reporting features that are not necessarily common, a general problem in corpus studies (Swales, 2002), a strict set of criteria have been applied to all the grammatical features here. The feature had to be used by five speakers of different first languages, in both lectures and group work, for a minimum of ten times. Only the features that fulfilled these conditions were included in the findings, as candidates for “commonalities.”

The following are the features that met the requirements, and are therefore presented as the commonalities of ELF grammar, accompanied with examples from the material, in Table 1:

Table 1 The grammatical commonalities found in the present material

<i>Grammatical commonalities</i>	<i>Examples from the material</i>
Not marking the plural on the noun	<i>They have a range from 50 to 500 meter. Typically you want to have five kilogram of oxygen. For example, you take two piece of glass.</i>
Article usage	<i>Superfluous or incorrect articles You will have a efficiency curve . . . If you go to the Belgium, all the highways are lit. You can use it in the different ways. Missing articles From those figures, you can have ▼ idea what reasonable speed . . . You can add timing interphase for ▼ memory system. Who has paid for the infrastructure? That's always ▼ interesting question.</i>
Double comparative/superlatives	<i>Much more safer, much more wider, more bigger, the most cheapest available biowaste.</i>
Subject-verb agreement	<i>I will talk about how a turbine operate in the system. However, the blades was not that good developed. There is a further method which are sensitive to porosity in rocks.</i>
Tense and aspect issues	<i>A Francis turbine is using the whole turbine equation (instead of uses). Typically the energy of the sun is emitting . . . (instead of emits).</i>
Passive voice	<i>They are not directly affect by these concentrations. It can be happened that sometimes . . .</i>
Nonstandard question formulation	<i>Why is such a difference in the diagram here between the blue and the red then? (missing “there”) Why is not good to combust directly? (missing “it”) Why this quotation only on one side? (missing helping verb) Why the function looks like that? (usage of “do”) What other equation I would use? (word order in questions)</i>
Word order	<i>I don't know what is the aim. We can't judge how solid is the ground. Here you see how does it look like.</i>
Negation	<i>It is a not very good generator. It has not always a low complexity. This point is supposed to not move.</i>

There were nine types of grammatical commonalities in the present setting, as displayed in Table 1. Among the features, the only one that disturbed communication was non-standard question formulation (Björkman, 2008a, 2008b). On this note, ELF usage in this instructional setting shows a considerable level of nonstandard grammar that does not interfere with communicative effectiveness.

The features found in this example ELF setting could be subsumed under the following categories in terms of their communicative effectiveness: (a) nonstandard usage that leads to overt disturbance in communication, that is, nonstandard question formulation; (b) successful reductions of redundancy, for example, not marking the plural on the noun; (c) devices that increase comprehensibility and create extra explicitness, for example, unraised negative (see “negation” in Table 1); and finally (d) other nonstandard features that do not interfere with communication (see Table 3). Categories (b) and (c) seem to be strategies speakers in lingua franca settings employ to get the message across.

Based on these results, transparency seems to emerge as a characteristic of grammar usage in ELF settings. The grammar features appear to be based on functionality. It seems reasonable to suggest that the features that serve a function seem to be preferred by speakers in lingua franca settings whereas those that are redundant are dropped, for example, third person -s. A feature is kept if it does not interfere with communication, if it aids communication, and is functional.

Critical Issues on the Grammar of ELF

How Common Are ELF Commonalities?

A critical issue on the commonalities of nonstandard grammar reported in Table 1 and elsewhere is how common, or uncommon, they actually are in comparison to standard forms. Apart from a few studies (Meierkord, 2004; Breiteneder, 2005; Ranta, 2006; Björkman, 2010), this issue remains relatively neglected in the ELF enterprise.

Table 2 gives the frequency of the grammatical commonalities found in the Swedish setting referred to here, comparing the standard and nonstandard production in lecturer speech and student group-work, both from instructional discourse.

Table 2 The standard versus nonstandard usage of the grammatical features in percentages

	<i>Usage in lectures</i>		<i>Usage in group-work</i>	
	<i>Standard usage</i>	<i>Nonstandard usage</i>	<i>Standard usage</i>	<i>Nonstandard usage</i>
Not marking the plural on the noun	94%	6%	82.5%	17.5%
Article usage	98%	2%	95.2%	4.8%
Double comparative/superlatives	99%	1%	98%	2%
Subject-verb agreement	98%	2%	98.2%	1.8%
Tense and aspect issues	98.5%	1.5%	100%	0%
Passive voice	96%	4%	85.2%	14.8%
Nonstandard question formulation	94.5%	5.5%	81.2%	18.8%
Negation	98.2%	1.8%	98%	2%

The figures reveal, rather strikingly, the very low frequency of these features in the present material. Only a minority of instances were nonstandard. The results of the present investigation indicate that variability is a characteristic of ELF usage. These results indicate that ELF is not a variety, if it is the traditional meaning of the term *variety* to which one intends to refer.

Regardless of the type of variation in usage, a set of solid features, referred to as “common core” (Quirk, Greenbaum, Leech, & Svartvik, 1985, p. 16), is required that cut across an entire variety. However esoteric a variety may be, it has running through it a set of grammatical and other characteristics (Quirk et al., 1985, p. 16). In this sense of the term, as regards grammar, ELF usage does not constitute a variety, for there is variability of usage and the ratio of nonstandardness over standard features is relatively low.

The Grammar of ELF With Reference to World Englishes, Creoles, and Learner Language

A critical issue to address here is the resemblance of the so-called ELF features to some varieties of English. The lists presented here and by Seidlhofer (2004, p. 20), have considerable overlap with the features of World Englishes, creoles, and learner language. A quick run-through of five different sources on the features of World Englishes (Crystal, 1995; Mesthrie, Swann, Deumert, & Leap, 2001; Mesthrie & Bhatt, 2008), creoles (Crystal, 1995; Mesthrie et al., 2001; Mesthrie & Bhatt, 2008), and learner language (Swan, 1980; Hultfors, 1986) reveals forms that cut across these groups, as shown in Table 3.

The comparison in Table 3 is by no means exhaustive, and it is not a review of a large number of sources. The aim here was not to outline all the features that run across all the reported features of World Englishes, creoles, and learner language, which would be beyond the scope of this entry and would need to touch upon issues such as language contact, variation and change, linguistic norms and their acceptability, ownership of the language, and expression of social identities (Seidlhofer, 2009, p. 236). The present list took the features found in the sample Swedish setting as the basis and checked whether the same features were found by other sources in World Englishes, creoles, and learner language. Although it is a relatively quick run-through of few sources, these overlaps do surface.

It seems reasonable to suggest that the reason for these overlaps is not that these language forms are all the same, but that it is due to the demands of functional communication. A close analysis of the types of nonstandard usage in the present setting reveals more than merely nonstandardness; there are tendencies such as increasing explicitness, for example, unraised negation, reducing redundancy, and dropping the third person -s. If a feature shoulders an important role in communication, that is, if it is communicatively dynamic, it seems to be retained whereas in the opposite case, it is omitted.

This review also answers the question whether ELF usage is *sui generis*, a question of debate raised in a number of studies. The features that cut across World Englishes, learner language and ELF settings show clearly that ELF usage is formally not *sui generis* since none of these features are unique to ELF usage. If ELF were *sui generis*, there would be very large numbers of unique and consistent nonstandard usage without any variability. This is not the case in this setting or in the literature. It is quite remarkable that apart from a few studies, ELF research has neglected to consider this.

Conclusion

In this overview, the focus has been on grammar usage in ELF settings. The existing research has shown certain types of nonstandardness and certain patterns of grammatical choice, pointing to a strong association between the grammatical choices and effectiveness

Table 3 The types of variation of grammar found in an ELF setting, in World Englishes features, creoles, and learner language

<i>Types of variation in grammar</i>	<i>A sample ELF setting from instructional discourse</i>	<i>World Englishes</i>	<i>Creoles</i>	<i>Learner language</i>
Nonstandardness that causes overt disturbance	Nonstandard question formulation	—	—	—
Devices that increase comprehensibility and create extra explicitness	Pre- and Post-dislocations/ Heads and Tails	Y (Mesthrie et al., 2001, p. 307; Mesthrie & Bhatt, 2008, pp. 81–82)	Y	Y (Swan, 1980, p. 498)
	Double comparative/ superlatives	Y (Mesthrie & Bhatt, 2008, p. 85)	Y	—
	Unraised negation	—	—	—
Reductions of redundancy	Not marking the plural on the noun	Y	Y (Crystal, 1995, p. 347; Mesthrie & Bhatt, 2008, p. 52)	—
	Subject–verb agreement issues	Y	Y (Crystal, 1995, p. 347; Mesthrie & Bhatt, 2008, pp. 65–66)	Y
	NonS analytic comparative	(Mesthrie & Bhatt, 2008, p. 85)	—	—
Other nonstandard features	NonS word forms	Y	—	Y (Hultfors, 1986, p. 148)
	Tense and aspect issues	Y	Y (Mesthrie & Bhatt, 2008, p. 60)	Y (Swan, 1980, pp. 414–430, 457–463; Hultfors, 1986, p. 96)
	Passive voice	Y	Y	Y (Swan, 1980, pp. 407–414)
	Word order	Y	Y/N Question word order not included (Mesthrie & Bhatt, 2008, pp. 78–81)	Y/N Question word order not included (Hultfors, 1986, p. 139)
	NonS Plural forms/ countability	Y	Y (Mesthrie & Bhatt, 2008, p. 52)	Y (Swan, 1980, pp. 137, 138; Hultfors, 1986, p. 59)
	Article usage	Y	Y	Y (Hultfors, 1986, pp. 42–56)

Y stands for “Yes” and indicates the presence of that particular feature.

in ELF usage. It is, however, critical that we acknowledge the low proportion of such usage in any discussion of grammar, as well as overlaps of ELF usage with World Englishes, creoles, and learner language.

Grammar: Overview

KARIN AIJMER

In a section on applied linguistics and grammar it is appropriate to start by considering what we mean by grammar and how our conception of grammar has changed as a result of developments in linguistic theory. Functionalist theories of language have for instance drawn attention to the uses of language and how grammatical features can be explained in terms of their functions. For the purposes of applied linguistics it is important to have a broad understanding of grammar which includes both syntactic structures and their uses. Moreover we have witnessed a change from prescriptive to descriptive grammar. Modern grammars are usually descriptive. *DESCRIPTIVE LINGUISTICS* describes the grammatical system at large based on the observation of how grammatical structures are used. A prescriptive approach to grammar, on the other hand, embodies the idea that only some grammatical forms are correct (see *PREScriptive AND DESCRIPTIVE GRAMMAR*). A descriptive approach has provided the model for scholarly grammars such as Quirk et al. (1985), Huddleston and Pullum (2002), Biber, Johansson, Leech, Conrad, and Finegan (1999), and Carter and McCarthy (2006).

Grammar is often treated as invariant. However there is not “one English grammar” but language varies across contexts of use. The study of spoken English has for instance shown that there is a grammar of conversation which is distinct from the grammar of other varieties. In this overview, the first part of the discussion will concentrate on functional and formal approaches to grammar. This discussion will be followed by a section on *CONVERSATION GRAMMAR*. The next section will contain a description of grammar in different varieties. In the last section the discussion will concentrate on how grammatical theory and innovations such as the use of corpora are relevant to language teaching.

Functional and Formal Approaches to Grammar

The state of the art in grammar is characterized by a controversy between *FORMAL AND FUNCTIONAL APPROACHES TO GRAMMAR*. The formal approach to grammar is exemplified by Chomsky’s model of transformational, *GENERATIVE GRAMMAR*. Generative grammar focuses on the speaker’s “competence” rather than performance and describes competence as a set of innate syntactic rules which function independently of external factors in the environment.

Functional models on the other hand are concerned with how language is used in communication and how grammatical phenomena are affected by social, pragmatic, or contextual factors. Functional models include *SYSTEMIC FUNCTIONAL LINGUISTICS* whose founding father is Michael Halliday. According to Halliday, language is shaped by its use in sociocultural settings and is part of a system of “social semiotics.” In this system language has three metafunctions depending on whether it is associated with human experiences (ideational function), the interaction with others (interpersonal function), and the organization of the message with regard to information structure and cohesion (textual function).

FUNCTIONAL GRAMMAR is a theory of language use originally developed by the late Simon C. Dik and his associates at the University of Amsterdam. The aim of functional

2 GRAMMAR: OVERVIEW

grammar is to develop a formal system where the formal categories are functionally and pragmatically motivated and described in a rigorous and explicit way. Compare Butler (2003) for a discussion of other members of the functional family of grammars including the Role and Reference Grammar developed by Foley and Van Valin (Foley & Van Valin, 1984). COGNITIVE GRAMMAR can also be regarded as functional since the uses of language in text and discourse are essential to this approach as well. However the view on linguistic categories as prototypical continua with a core and periphery is special to this approach.

In many linguistic theories and approaches lexis (vocabulary) and grammar are not seen as separate components but as interacting with each other (LEXICOGRAMMAR). In a lexically driven approach to grammar the emphasis is on the patterns of structure and use. PATTERN GRAMMAR (Hunston & Francis, 2000) categorizes words into patterns on the basis of their co-occurrences with other words. Hunston and Francis found, for example, that there is a restricted number of English verbs such as *think*, *know*, *see* co-occurring with *that*-clauses. Their findings were based on the empirical analysis of the collocational patterns of the verbs in large electronic corpora.

Biber et al. (1999) have shown on the basis of large-scale corpus investigations that recurrent word combinations can be of different length and that they do not need to be grammatical units. So-called lexical bundles (see LEXICAL BUNDLES AND GRAMMAR) are illustrated by *I don't know why* or *can I have a*. They are interesting for language teaching since learners have to produce chunks of idiomatic English. Words can also be associated with a special lexicogrammatical environment. SEMANTIC PROSODY can for instance explain how a word or construction carries with it an evaluation that something is bad (*in case of fire*).

LINEAR UNIT GRAMMAR represents another departure from traditional descriptive models of grammar. The emphasis is on conceptualizing how the message is divided up into units which are easy to process ("chunks") and how grammar is basically linear rather than hierarchical. Linear unit grammar is essentially a contribution to the description of spontaneous speech and has a number of applications for communicative teaching and interpreter education.

The interest in the relationship between GRAMMAR AND DISCOURSE has led to research into METADISCOURSE, that is, linguistic features commenting on the content of the text. Metadiscourse is an important feature of academic discourse, especially academic writing (see GRAMMAR IN ACADEMIC WRITING). CONNECTIVES (e.g., lexical items such as *however* and *furthermore*) are studied in applied linguistics because they express semantic and formal relations contributing to the coherence of discourse. Linguistic features may also be associated with the INFORMATION STRUCTURE. Speakers and writers may for instance change the order of words in order to present something as new or given information.

Conversational Grammar

For a long time grammars dealt with written language only and spoken language was regarded as inferior to writing. There is now a growing awareness of the importance of spoken language and the difference between the grammar of conversation and the grammar of Standard English. In CONVERSATIONAL GRAMMAR the forms are understood in terms of their accommodation to the conditions under which conversation takes place, for example, the temporal constraints making it impossible to retrace one's steps.

Many pragmatic phenomena such as pragmatic markers are closely associated with their occurrence in conversation. Pragmatic markers are little words such as *you know*, *I mean* whose function in conversation is to maintain harmonious relations between the

participants and to prevent disruptions in conversational coherence. However, the relationship between PRAGMATIC MARKERS and grammar is controversial since pragmatic markers are “inserts,” that is, they are placed in a special slot outside the proposition (Biber et al., 1999). Pragmatic markers are closely associated with fluency and with nativeness and should not be ignored in textbooks and in classroom teaching.

The term SPEECH ACTS was first used by philosophers interested in “how to do things with words” (Austin, 1962). Grammarians interested in functions refer to the speech act functions associated with sentences, for example, asking someone to do something (*can you open the window*). Functions such as requesting can be expressed both directly (by an imperative) and indirectly by means of a question.

A speech act can be mitigated by HEDGES in order to make it more polite. The notion hedge refers to a broad category of words “which make things fuzzier or less fuzzy” (Lakoff, 1972). However, the term is also used to describe the mitigating (or reinforcing) force of speech acts.

We notice finally that many traditional categories such as ADVERBS and TENSE AND ASPECT can have discourse functions. Changes in tense or aspect can for instance be used to signal what is background or foreground in a narrative. MODALITY can be interpreted broadly as a pragmatic notion referring to speaker attitudes. The prototypical modal forms are the modal auxiliaries but modality can also be realized by adjectives, adverbs, lexical verbs, or pragmatic markers.

Grammar and Variability

Grammatical structures are not stable but can vary depending on a large number of variables. These variables can be traditional sociolinguistic factors such as age, gender, and class. “Change in progress” may be first seen in the language of adolescents (see GRAMMATICAL VARIATION IN ADOLESCENT LANGUAGE). A much discussed ongoing change which is both regional and spearheaded by adolescents is for instance the use of *be like* as a quotative introducing reported speech (Andersen, 2001). Social class (see GRAMMAR AND SOCIAL CLASS) is another variable which has been studied with regard to phonology and morphology and to a lesser extent with regard to grammar. The influence of society and culture on grammar (see GRAMMAR AND THE INFLUENCE OF SOCIETY AND CULTURE) is studied in the field of “ethnosyntax.” According to Wierzbicka (e.g., 1979), who uses the term, grammatical structures can encode ways of thinking specific to a certain culture. The study of CROSSLINGUISTIC DIFFERENCES IN GRAMMAR may also be of interest to applied linguists since the differences may result in transfer. REGISTER focuses on language variation due to the situation of use. Typical registers each with characteristic grammatical and lexical features are, for instance, doctor–patient communication (see GRAMMAR AND DOCTOR–PATIENT COMMUNICATION), political debate (see GRAMMAR IN POLITICAL DEBATE), or the law (see GRAMMAR IN THE LAW). Academic writing (see GRAMMAR IN ACADEMIC WRITING) is included among languages for special purposes and the research article (see GRAMMAR AND THE RESEARCH ARTICLE), abstracts, proposals, and so forth, are regarded as special genres each with their own grammatical and lexical features.

A number of changes have affected the grammar of electronic communication (see GRAMMAR AND ELECTRONIC COMMUNICATION) used in chatrooms and blogs on the Internet. The interest in the grammar of literature (see GRAMMAR AND LITERATURE) and its special properties has now developed into a new discipline of literary stylistics. It explores the use of linguistic methodologies in the analysis of the language of literature as well as in other types of text such as recipes or advertisements.

Grammar and Language Acquisition

There is an ongoing debate about how children acquire grammar centering on innateness versus learning by observation. This is discussed in the entry on the **FIRST LANGUAGE DEVELOPMENT OF GRAMMAR**. Conversely, **LANGUAGE ATTRITION** refers to the loss of grammatical features, for example, as a result of aging or the loss of grammatical features in L1 by L2 speakers.

Language teaching is a major area in applied linguistics. Grammar instruction in second and foreign-language teaching is by tradition very strong as pointed out in the entry on **GRAMMAR IN LANGUAGE TEACHING AND EDUCATION**. However, there is little agreement about the best approach to teaching grammar and the pendulum has moved back-and-forth between deductive and inductive teaching methods. In recent years grammar teaching methods have also been influenced by the availability of corpora (Aijmer, 2009). See also the discussion of different uses of corpora in the entry on **TEACHING GRAMMAR AND CORPORA**.

Grammar is often neglected in language programs in the workplace in favor of the teaching of communicative skills but grammatical correctness is central to the achievement of communicative competence (see **GRAMMAR TEACHING AND THE WORKPLACE**). However, the goals relating to correctness in the use of language may differ if the speakers are non-native speakers communicating with native speakers or if they are speakers using English as a lingua franca to communicate with other non-native speakers (**GRAMMAR OF ENGLISH AS A LINGUA FRANCA**).

Finally, we need to mention some foreground figures who have made major contributions to the description of the uses and structures of language and have therefore been important in applied linguistics. This section contains biographical notes on Geoffrey K. PULLUM and Ruqaiya HASAN.

Greenbaum, Sidney

CHRISTIAN MAIR

Sidney Greenbaum (1929–96) was born in London on December 31, 1929, a member of East London's orthodox Jewish community. Already holding BA and MA degrees in Hebrew and Aramaic (University of London) and a religious minister's diploma from Jews' College, he obtained a Postgraduate Certificate in Education in 1954 and worked full time as a primary school teacher for a number of years. During this period he managed to keep up his academic interests in the study of languages and language but increasingly refocused them on the subject of English (BA Hons, 1957). In 1965 he joined the Survey of English Usage at University College London where he completed his PhD under the supervision of his mentor and subsequent collaborator Randolph Quirk. The degree was conferred in 1967 and the thesis published in 1969 as *Studies in English Adverbial Usage*—the start of an academic career which took him to the United States for an extended period. For most of this time in the USA his academic home was the University of Wisconsin at Milwaukee, which he joined in 1969 and left as a full professor in 1983 when he returned to London to succeed Randolph Quirk as Quain Professor of English. He retired in 1990 while continuing to serve as a research professor and director of the Survey of English Usage until his untimely death on May 28, 1996 during a lecture tour through Russia. As a human being, Sidney Greenbaum presented a complex personality: sociable at conferences, lovably eccentric and generous with his advice on some occasions and to some of his colleagues and students, withdrawn into himself and less than conciliatory with others.

Sid Greenbaum's contributions to applied linguistics, and in particular to corpus-based applied linguistics, are twofold. Throughout his professional career, like his mentor Randolph Quirk, he was a mediator between the professional linguistic establishment and a general public keen on advice on matters of English usage; in the last few years of his life he successfully launched the International Corpus of English (ICE), the first corpus project allowing for serious and comprehensive comparative research on the "old" and "new" Englishes.

As a grammarian with a readership extending far beyond academia, he was tireless in making the case for an enlightened contemporary notion of "good English" which was to be based on solid documentation and analysis of empirical language data, and no longer on the haphazard collection of prescriptive folklore handed down from the past. His specific contribution to descriptive linguistic research on English grammar was the combination of corpus analysis and systematic elicitation of native-speaker judgment and performance. In its meticulous attention to detail, a work such as *Elicitation Experiments in English: Linguistic Studies in Use and Attitude* (1970, coauthored with Randolph Quirk), detailing the ingenious ways in which such elicitation experiments can be set up, is a model even today. *Good English and the Grammarian* (1988a), the title of a collection of essays, might well serve as the motto informing this side of his work.

As a coauthor, with Randolph Quirk, Geoffrey Leech, and Jan Svartvik, of *Grammar of Contemporary English* (1972), the subsequent *Comprehensive Grammar of the English Language* (1985), and their several spin-offs, he secured a position for himself among the most eminent grammarians of the English language. Success within academia, however, was never sufficient for him and in numerous publications he appealed to a general literate public. For

example, *Oxford English Grammar* (1996) admirably combines accuracy of description and accessibility to the lay reader. It is in this work, incidentally, that he states his notion of good English most clearly, arguing that

good English is sometimes equated with correct English, but the two concepts should be differentiated. Correct English is conformity to the norms of the standard language. Good English is good use of the resources available in the language. In that sense we can use non-standard dialect well and we can use standard language badly. (Greenbaum, 1996a, p. 17)

In applying this insight in works such as the revised version of Sir Ernest Gowers's classic *The Complete Plain Words* (1987) and the *Longman Guide to English Usage* (1988, with Janet Whitcut), Sidney Greenbaum, the mediator, placed great emphasis on detailed analysis and steered clear of the type of wholesale condemnation of the prescriptive tradition which would have alienated an at least partially conservative readership.

On assuming the directorship of the Survey of English Usage, the institution where he had started his academic career as a research assistant almost twenty years before, he seriously began to explore for himself the potential benefits of digitizing corpus data and analysis—a rather profound re-orientation for someone who, as he did, felt more comfortable in the position of the philologist than the computational linguist and data cruncher. His very own and original contribution to applied corpus linguistics is the creation of the ICE, designed to make possible systematic comparison of regional varieties of standard English, including second language varieties and varieties with a creole substrate, over a wide range of spoken and written textual genres (Greenbaum, 1988b, 1996b). When the idea of ICE was first floated in the early 1990s, it was met with skepticism if not mild mockery by some in the corpus-linguistic community who felt that there was little point in compiling another set of “small” one-million-word corpora at a time when other research groups were embarking on the compilation of the British National Corpus, with its 100 million words. More sociolinguistically minded critics, on the other hand, tended to point out that there was no way of ensuring that a particular text sample collected could be said to “match” its equivalent from another corpus in constellations as diverse as monolingual native-speaking New Zealand and multilingual English-using India or East Africa.

While Sidney Greenbaum spared no effort to recruit collaborators from around the globe and get other projects on their way, his own attention was devoted to the British component, ICE-GB. An assiduous and successful fund-raiser, he managed to secure the resources to produce a corpus which is searchable as plain text, but also with part-of-speech annotation and syntactic parsing, with integrated project-specific software allowing access to the material in very sophisticated ways at all levels. This gold standard of corpus compilation and annotation serves as a benchmark for the other ICE teams, even though it has not quite been reached by any of them. However, it is testimony to Sidney Greenbaum's foresight that the ICE project continued to grow even after his premature death and that now there are 10 additional subcorpora which are completed and available to the linguistic community (Australia, Canada, East Africa, Hong Kong, India, Ireland, Jamaica, New Zealand, Philippines, Singapore), and several others which are in the making at various stages of completion at the time of writing (2010). Most prominent among these and the most eagerly awaited is ICE-USA, but also Canada, Fiji, Malta, Nigeria, and South Africa, among others. As documentation of the speech of educated “model” users of English in these various contexts, the corpora have enormous potential when it comes to issues such as devising realistic norms of English in education in second language contexts or, more generally, modeling the “pluricentricity” of standard English in the 21st century. The latest use to which ICE-GB was put (by Sidney's doctoral student and successor as director

of the Survey of English Usage, Bas Aarts) was to combine it with parts of the London–Lund Corpus to produce the Diachronic Corpus of Present-Day Spoken English (DCPSE), the first corpus which makes possible research on diachronic developments in spoken English in “real time.”

Grounded Theory and Qualitative Research

DEBORAH R. DILLON

What Is Grounded Theory?

“Grounded theory” (GT) is a term used by many researchers to describe a general method of developing theoretical constructs inductively from data sources gathered as part of a qualitative research study. This method is in contrast to initiating a research study with a particular theory that one wants to prove or disprove, and then collecting data to support the preselected theory. It is also different from a qualitative study that is essentially descriptive analysis. Briefly, within the general view of “a GT approach,” researchers conduct inquiry to generate theory inductively from data collected, typically using a “construct-oriented” approach (e.g., creating categories that describe patterns in the data). They accomplish this by using systematic and thorough procedures. As researchers collect data, they simultaneously analyze these data using induction, deduction, abductive reasoning, and verification to develop theory. This theory provides a full explanation of a process or scheme associated with particular phenomena. During the analytical process, researchers become more familiar with the data and develop hypotheses, insights, and questions that are used to drive further data collection and analysis, and refinement of the theory. A visual model is produced from the analysis that displays a coding diagram of the theory, and the tone of the research indicates that a scientific process has been undertaken, while also being sensitive to the data and ideas generated from it (Creswell, 1998, p. 43).

While GT is appropriate for many qualitative studies, scholars in the field would argue that there are important differences between GT as *an approach or general method* and GT as *methodology* (GTM). The latter is not only a perspective or approach for developing theoretical ideas, but also includes attention to the philosophical and theoretical perspectives held by the researcher that undergird the study (Bryant & Charmaz, 2007; Birks & Mills, 2011). GTM also rests on a set of procedures for conducting research, including how data are analyzed and how theory is developed and reported. However, the idea that there is one approach to doing GT research is open to debate, and some researchers believe that theory generation—while important—is not the only benefit that results from GT studies (see Corbin’s introduction to Corbin & Strauss, 2008). Researchers can also use this approach to develop rich analyses of complex phenomena to address a wide array of research problems. As Corbin noted (Corbin & Strauss, 2008), a set of concepts provides a useful common language that researchers can work from as they build a body of knowledge and seek to impact practices. For the purposes of this entry, GTM as a detailed methodology and way of generating theory will be described.

What Are the Origins of Grounded Theory Methodology?

GTM is a well-developed set of procedures or analytic techniques designed with a particular end in view: creating a formal, substantive theory that explains a particular sort of social phenomena. GTM is based on the tenets of field research, where investigators “seek

2 GROUNDED THEORY AND QUALITATIVE RESEARCH

to move beyond particular meanings to identify general patterns and regularities in social life" (Charmaz, 1983, p. 93). Generating theory, then, requires that we take what we learn from observations and interactions with participants and indicate what these data tell us about the group upon which they are based, and about the social life of similar groups. Working between generating theory and staying true to the specific phenomena and participants under study provides a creative tension that researchers work within.

A rich history and database are associated with GTM. The database is used by many researchers and has resulted in a large number of publications in journals across many discipline areas. GTM was developed collaboratively by Drs Barney Glaser and Anselm Strauss (now deceased). Strauss studied at the University of Chicago and was greatly influenced by interactionist and pragmatist thinking. Thus, GTM is deeply rooted in the field of sociology, and these ideas became its foundational premises. Symbolic interactionist ideas relate to studying the empirical social world, the world of everyday experiences and group life, looking to understand what people experience and do (Blumer, 1969). A study of the empirical social world begins with the act of inquiry, by asking questions about the world under study; researchers then use the information gathered from these questions to formulate problems that will be examined and will guide inquiry. The analyst's work is to view the problem under study through a flexible lens, free to shift as new knowledge is gained, in order to correctly situate the phenomena under study. Because of premises such as its focus on understanding the nature of experience, the importance placed on generating theory grounded in reality, and the belief that researchers must get into the field in order to understand phenomena, GT is termed *fourth generation symbolic interactionism* (Denzin, 1992).

Strauss worked with Glaser on a seminal study designed to study the experience of dying, and it was through this work that the methods outlined in the seminal text *The Discovery of Grounded Theory: Strategies for Qualitative Research* (Glaser & Strauss, 1967) were generated. These initial ideas evolved in scope on the basis of new ideas and research studies (Glaser & Strauss, 1978), primarily developed by students of the two scholars. Glaser left academia to pursue publishing and consulting work worldwide. The two scholars interacted again when Strauss and his student Juliet Corbin published the *Basics of Qualitative Research: Grounded Theory Procedures and Techniques* (1990). Glaser's writings indicate a different perspective on GT than his colleague's, focusing on GT as a method and on the substance of the resulting theory that emerged. Glaser did not focus on the use of any particular philosophical or theoretical underpinnings to the research because he felt this diminished the potential of GT by constraining the researcher. Instead, he focused on the process of induction, and the researcher's skills and creativity in developing emerging categories from the data, seeking objectivity through the examination of multiple cases of a phenomenon under study. In contrast, Strauss was more interested in validation criteria and developing systematic approaches to doing research, by focusing on GT as a set of strategies and techniques that researchers could draw from when engaged in inquiry.

Historically, researchers have discussed what are called "moments" in qualitative research and the place that various GT approaches hold within this system (Denzin & Lincoln, 2005). Most agree that GT started in the "second moment" when the 1967 book was published. Later works, such as Strauss and Corbin's work, were critiqued as lacking attention to ontological and epistemological issues such as how researchers view the world, what counts as knowing and understanding phenomena under study, and the role of the researcher—all needed to design a high-quality study (Birks & Mills, 2011). Subsequently, GT researchers developed theoretical frameworks that GT methods and methodology are embedded within. Corbin and Strauss (2008) enlarged their discussions of GT by attending to philosophical issues such as pragmatism and interactionist theories from the Chicago Sociology traditions, themes that Strauss actually outlined years earlier (Strauss, 1987). The

focus on pragmatism influenced the development of axial coding, with this perspective serving as a focal point for the grounded theories that these researchers developed (Kelle, 2005). Researchers note that GT has moved to a “fifth moment” in which attention is paid to the role of the researchers with participants, the importance of writing and grounding the final write-up in the data, and the outcomes of this research particularly in terms of evoking change in society. Charmaz (2005, 2006) argues that GT methodologists need to move beyond the positivist origins of GT and incorporate many of the methods and questions posed by constructivists over the past 20 years as well as by social justice theory advocates. She believes that this will allow researchers to become more nuanced and reflexive in their practices, and impact social change. Several educational researchers continue to draw upon a pragmatist’s perspective to undergird GTM, in which researchers study practical problems, identified by participants or in the field, and the goal is to press change to improve situations and individuals’ lives (see Dillon, O’Brien, & Heilman, 2000).

How Is Grounded Theory Methodology Carried Out?

Glaser and Strauss’s seminal text, *The Discovery of Grounded Theory*, documented in detail the procedures for engaging in GT research, and these ideas were embellished by various researchers in later years. First, data are collected in a variety of forms such as interviews, observations, field notes, documents, and conversations. These data are analyzed with the goal of developing *concepts* or *conceptual categories* that describe basic social processes, and are supported by *properties* that describe the qualities of the categories. To generate the categories and properties, researchers engage in *open or substantive coding*. They read their data and begin to code all different types of actions, events, and processes—anything related to the research questions guiding the study—and write analysis notes in the margins of the documents they are working on. This process is time-consuming because the researchers are carefully coding many concepts as they work through considerable numbers of data. Second, the initial codes the researcher generates from data are compared to new codes that are identified in new data that are collected. This often results in the merging, modification, and clarification of codes. This back-and-forth, cyclical process of comparing new data with previous data that have been collected and coded is called *constant comparative analysis*. The process also sets the stage for *core codes* to be developed and initial theory to be formulated. Strauss and Corbin (1990, 1998) outline a third step where the researcher engages in *axial coding*, wherein data are put together in new ways after open coding, allowing the researcher to make connections between categories. In particular, the researcher selects one open coding category, places it as the central phenomenon, and then relates all other categories to it.

During these analytic processes, researchers look at “conditions, context, action/interactional strategies and consequences” (Strauss & Corbin, 1990, p. 96) as they code data. By this point in the analysis process, the researcher is ready to commit to a set of core codes. The next step is for researchers to use *selective coding* of data, using the set of core codes to guide the coding and filtering out of data that have little importance to the core categories and supporting properties. Note, the filtered-out data are not totally discarded. Instead, they may be used to test the constructs later in the process or provide discrepant or conflicting explanations of events or actions.

Once a large enough number of the data have been carefully analyzed in this manner, researchers begin to selectively sample new data that are collected, using the core codes. This is called *theoretical sampling* and is followed by the development of *theoretical codes*, or the process of connecting theoretical ideas to the data. Researchers know that theoretical sampling and coding are key to seeing how various concepts come together into a

theory that addresses one's research purpose and questions. It is important that these theories are not introduced too soon, but are developed carefully during the analysis process. Often theories are conceptualized and clarified *theoretical memoing*, or the creation of notes and maps or drawings that a researcher develops during analysis. Glaser (1978), in particular, discusses the importance of memoing, reporting that "Memos are the theorizing write-up of ideas about substantive codes and their theoretically coded relationships as they emerge during coding, collecting and analyzing data, and during memoing" (1978, p. 83). Glaser and others (Wolcott, 1990; Alvermann, O'Brien, & Dillon, 1996) also indicated that it is critical to engage in memo and other forms of writing early and often during data collection and ongoing analysis of data. When researchers write and sort memos, they are engaged in a critical process that allows new ideas to emerge and the connection of ideas, leading to a theory that intricately explains the phenomenon under study. In the final product, the categories and properties generated throughout the data analysis processes, along with the theoretical memos, are used to explain conditions, context, action/interactional strategies, and consequences. Tables, figures, and data excerpts are used as evidence to support the write-up, and the theory generated is linked with the existing literature in the field. What follows is an example of GTM in action, to serve as an illustrative case of the specific processes a researcher undertakes when engaging in this form of inquiry.

Grounded Theory in Practice

In Dillon's dissertation research (1985), later reported in Dillon (1989), she reports on a year-long GT study of one teacher and his students in a low-track secondary English-reading classroom in rural Georgia. Her research purpose was to generate a description and interpretation of the social organization in the classroom. Of special interest in this study were the actions and patterns of actions the secondary teacher displayed during daily classroom lessons, how these actions were formed and influenced by the students' actions, and how the actions impacted the social organization of the classroom and the cognitive and affective learning of the students. Four research questions guided the data collection:

1. What is the nature of the social organization in the observed classroom?
2. What verbal and nonverbal actions/patterns of action does the teacher display as he interacts with students that have low reading ability? How does the context of the learning situation/social organization influence the teacher's actions/patterns of action?
3. How does the teacher perceive and interpret his own actions in various contexts involving students that have low reading ability? Does the teacher perceive his actions changing when working with students that have average or above-average reading ability?
4. How do the students in the observed class and administrators of the school perceive and interpret the actions of the teacher during lesson interactions?

Dillon merged an ethnographic approach, designed to address the classroom, school, and community cultural influences played out in the classroom, and a more fine-tuned classroom interaction analysis, addressed by the lens of symbolic interactionism (Denzin, 1978). Primary data for the study were collected in the form of field notes, and audio- and videotaped lesson transcriptions were collected during an exploratory phase from September through February on a weekly and two-weekly basis, and from March through May on a daily basis. In her role as participant observer, Dillon sat with the students during

class, participating in the activities; talking with them before, during, and after lessons; and writing field notes. Her daily site visits culminated in conversations with the teacher, Mr Appleby, after class, during his planning period. These primary data sources were triangulated with secondary data sources including (a) structured and informal interviews, (b) questionnaires, and (c) documents/artifacts.

Dillon collected and analyzed the data simultaneously using the constant comparative method (Glaser & Strauss, 1967). Her process involved combining inductive behavior-category coding with simultaneous comparison of all incidents observed, and was used with all data. Her daily analysis procedure consisted of fleshing out, reading, and rereading field notes; listening to and transcribing audio- and videotapes; looking for patterns of actions/meanings in the data; and reflecting on the data by writing theoretical memos (Glaser & Strauss, 1978) or analytic insights. She continued this process as she collected data, looking for incidents that confirmed or disconfirmed her initial assertions about the social organization in the classroom. These initial assertions included theories that Dillon thought undergirded Appleby's actions, in particular the delicate balance between teachers who help students learn and teachers who help students learn helplessness. Dillon constructed theoretical memos depicting her thinking processes as she tested assertions, and she looked for key linkages in the data connecting similar instances of the same phenomenon (e.g., her observation and interpretation of an event or action, as compared to those of the three key informants and Appleby). After the school year ended she continued to test and retest her assertions and the categories and properties that were emerging, examining and reexamining all data. Part of her analysis process included cutting apart one copy of all field notes and interview transcripts and placing common incidents together on colored sheets of paper—a separate color for each category. This process helped her display the data in order to count the number of incidents under each category to see if saturation had been reached. (Saturation is reached when a researcher has multiple instances of a phenomenon that occurs over several contexts and time frames, reassuring the researcher that she has evidentiary warrant to support an assertion.) She also continued to read the intact copies of the data to keep a holistic picture in mind. During the analysis process she asked Appleby to read, react to, and help her firm up the assertions and the categories, properties, and instances of data under these assertions.

The emerging theory that Dillon generated from the data analyses was that the social organization in the observed classroom was constructed jointly by Appleby and his students; Appleby assumed the role of translator and intercultural broker (Erickson, 1986) during teacher and student interactions. In this role, he worked to provide a bridge between students' home culture and school culture. He also interacted with students in ways that met their cognitive and affective needs. Thus, Appleby established an environment in the classroom that resulted in reduced resistance to learning and increased active participation during lessons. Dillon generated 11 categories, each with 5–10 properties (Dillon, 1985) that supported her theory. In a later analysis (Dillon, 1989), she took the 11 categories and consolidated these into three core interrelated categories: (a) Appleby established an open, risk-free environment; (b) he strategically planned and structured lessons to meet the interests and needs of his students; and (c) he implemented lessons in which all students could be active, successful learners. In her write-up, Dillon defined each category and provided evidence using vignettes, excerpts from field notes, interview comments, and documents. For example, for the category "Implementing lessons in which students can actively participate," Dillon showed how Appleby created the environment, planned the content to be learned, and structured lesson activities to promote students' active, meaningful learning. Three properties supported the category of implementing lessons where students could actively participate: (a) allowing students to use their natural language during lesson interactions and transforming the teachers' language to match that of his

students, (b) anticipating possible difficulties students might have with assignments and adapting lessons to meet the needs of students, and (c) bridging gaps or scaffolding between the background knowledge students had and new concepts and materials they were to learn. To show Appleby as scaffolding instruction (property [c] above), Dillon shared a clip from a lesson on *The Old Man and the Sea*. During these interactions Appleby helped students bridge the gap between a previously read portion of the story and the portion they were going to read next, and explained difficult vocabulary using verbal and non-verbal means.

Appleby: LaVonne, tell us a few things about the story thus far. How long has the old man been without fish?

(A group of students answer with LaVonne. Appleby asks LaVonne if she'd like to read aloud from the text—she agrees. As she reads Appleby stops her at the points he would have stopped at, and fills in information he believes his students need to know in order to understand the rest of the story.)

Appleby: Ok, bait, bait in this story is not like you may be used to. It's fish you use to catch other fish—not worms like some of you asked. (and a bit later in the lesson)

Appleby: Ok, turtle-ing—now this is how you used a ship with a crow's nest. (He stops to explain what a crow's nest is for a student that asks. Appleby also explained how bad the glare from the sun on your eyes was during the whole process.) (Lesson Transcription—4/30)

After this example, Dillon interpreted the data clip for readers, describing how Appleby attempted to build background knowledge for his students as they read by teaching vocabulary in the context of the story, in the belief that this is more meaningful for the students. Dillon concluded her overall analysis by bringing all the categories and properties together, weaving the emerging theoretical ideas she had generated as she presented her findings together for the reader. In the end, Dillon linked her emerging theory with previous research, and pressed the field forward in new directions—theoretically and methodologically—with her concluding section about what makes a teacher effective.

Deconstructing the Example

What criteria are used to determine the quality of GTM studies? The excerpt above shows how GTM was used by a qualitative researcher who worked to understand events in one context, over time, where large numbers of data were systematically collected and analyzed in an ongoing fashion. Initial speculations were compared with subsequent data, and the researcher used a variety of systematic analysis strategies to discern patterns in actions, events, and perspectives held by participants. The resulting assertions were larger units of explanation for what occurred in this classroom and why, and the categories and properties delved into facets of the assertion statement to illuminate specifics in the setting, thus offering stronger arguments for the assertion. Each category and property was clearly defined, and data excerpts that best illuminated that category or property were provided, usually from more than one data source.

The most important criterion used to judge GT studies focus on validity, although not in the traditional sense of this term. Studies are judged by whether the concepts (categories and properties) put forth closely fit the phenomena they purport to explain. A careful and thorough process of constant comparative analysis helps to ensure this result. In addition, the findings of the study should be relevant to the participants under study, and the theory should be workable in indicating how the problem is resolved or the phenomena under study are understood. In a strong study the theory can also be modified, through additional constant comparative analysis, to reflect new and relevant findings (Glaser &

Strauss, 1967; Glaser, 1978, 1992). Strauss and Corbin (1990) elaborate on these key ideas, indicating two levels of criteria for evaluating a GT study. The first level includes seven criteria and focuses on a series of questions that readers might ask as they read a study and that enables the readers to make judgments about the components of the research process and the resulting write-up. These questions focus on how the sample was selected, how major categories emerged, what evidence led to these, how the theoretical sampling process unfolded, what the emerging hypotheses were, and how and why core categories were selected. The second level of criteria focuses on the empirical grounding of the study and includes the following set of questions:

Are concepts generated? Are the concepts systematically related? Are there many conceptual linkages and are the categories well developed? Do they have conceptual density? Is much variation built into the theory? Are the broader conditions that affect the phenomenon under study built into its explanation? Has process been taken into account? Do the theoretical findings seem significant and to what extent? (Strauss & Corbin, 1990, pp. 252–7)

These researchers note that the criteria are guidelines, to account for future innovations in the field. But they follow this statement with a caveat, noting that it is critical for GTM researchers to be forthcoming with their research processes and procedures to help readers understand the quality and value of studies.

GTM is a substantive area of research and provides a flexible, yet carefully thorough set of procedures for researchers to use when trying to understand complex problems or events in context, and over time, where large numbers of data are collected and need to be systematically analyzed to result in an explanation that will be of use to the participants involved in the research. This approach continues to evolve to meet the needs of researchers and their interests (Charmaz, 2005), and when used by skilled and thoughtful researchers, it can advance many fields where it is employed.

Guilherme, Manuela

ALISON PHIPPS

Manuela Guilherme's contribution to applied linguistics is in the field of intercultural education and intercultural communication. She was born in Mozambique, in a highly multilingual and multicultural environment, and went to Portugal in order to graduate in German and English philology at the University of Lisbon. She worked there for many years as a foreign-language teacher and as a teacher educator. In 2000, after moving to the UK and studying at Durham University, she was awarded a PhD. Her PhD was a distinctive examination of Mike Byram's concept of *savoir s'engager*—knowing how to engage politically—which is elaborated in his *Teaching and Assessing Intercultural Communicative Competence* (Byram, 1997). Guilherme's investigations had previously involved, and continued to involve, substantial study visits to various universities in the USA, namely the California Foreign Language Project at Stanford University, Brown University, University of California (Davis), and California State University (Fullerton), among others, in order to carry out research on critical pedagogy within the context of bilingual education programs and intercultural communication. It also involved detailed empirical work with Portuguese teachers of foreign languages. It used both quantitative and qualitative methods in an innovative blend, and engaged a range of critical philosophical, pedagogic, and poststructural thought. She brought new influences to intercultural language education through combined study of Habermas, Derrida, Freire, and Giroux.

Guilherme's PhD thesis (Guilherme, 2000) was awarded the Emma Birkmaier Award by the American Council on the Teaching of Foreign Languages and the *Modern Language Journal* in 2001. This groundbreaking thesis marked the beginning of a distinguished academic career in critical intercultural language education with a particular focus on education for citizenship. Guilherme published her doctoral work as *Critical Citizens for an Intercultural World* (Guilherme, 2002) in the Multilingual Matters series *Language, Intercultural Communication and Education*, edited by Michael Byram and Alison Phipps. Her book remains one of the leading publications in the series and is recognized as a crucial and original contribution to work on critical intercultural citizenship. What distinguishes Guilherme's scholarship is her blend of practical application, empirical rigor, and theoretical synthesis. She combines considerable understanding of theoretical concepts with a critical outlook on language pedagogy to develop new models which can indeed be applied in classroom practice in language teaching. Her interdisciplinary model for teaching and learning foreign cultures is a significant and much-cited example (Guilherme, 2002). It combines the fields of intercultural communication, critical pedagogy, and intercultural communication to demonstrate how foreign-language teaching and learning index the development of critical citizenship. As such, and through this first monograph, Guilherme sets an agenda for foreign-language/culture education in Europe and the Global South, with the aim of bringing a critical agenda to a field dominated by functional approaches.

In 2001, Guilherme was appointed as a social scientist researcher at the Centre for Social Studies at the University of Coimbra, Portugal, a world-leading research center for critical and postcolonial interdisciplinary studies. Here she published a jointly edited special issue of the journal *Language and Intercultural Communication*, and a stand-alone edited volume,

Critical Pedagogy: Political Approaches to Language and Intercultural Communication, with Alison Phipps (Phipps & Guilherme, 2004). From Coimbra, she successfully coordinated two significant European projects:

- INTERACT—Intercultural Active Citizenship Education (VI European Framework and Fundação Calouste Gulbenkian) developed European work in the field of Critical Intercultural Citizenship: <http://www.ces.uc.pt/interact> (2004–7);
- ICOPROMO—Intercultural Competence for Professional Mobility, which focused on the development of intercultural competence for multicultural teamwork (Leonardo da Vinci Programme and the European Centre for Modern Languages, Council of Europe). <http://www.ces.uc.pt/icopromo/>; <http://www.ecml.at>

Both projects were marked by considerable empirical research and the development of modules and activities which would develop the critical awareness which, for Guilherme, is central to education for intercultural citizenship. Through the research and scholarship underpinning her primary conceptualization of both projects, elaborated through the team research, Guilherme went on to publish widely in the field. In 2010 an edited volume, *The Intercultural Dynamics of Multicultural Working* (Guilherme, Glaser, & Mendez-Garcia, 2010) was published, which brought new data and theory into the field of intercultural working and which drew on sociolinguistics, business communication, intercultural education, critical pedagogy, and foreign language pedagogy and brought critical perspectives into professional training for mobility.

As an associate professor and senior researcher at the Institute of Education, Universidade Lusófona de Humanidades e Tecnologias, Lisbon, Guilherme has been developing the concept of intercultural responsibility, that she proposed within the scope of the ICOPROMO project in order to further the term of “intercultural competence” in the European context. In addition, she is also involved in various European Union–Latin America research projects focusing on higher education development, as well as on citizenship and intercultural and language education, based mainly in Portugal, Spain, Brazil, and Mexico, where her doctoral empirical study questionnaire (2000) has now been implemented.

Haberland, Hartmut

BENT PREISLER

Hartmut Haberland (b. 1948) is a German-Danish linguist whose main contributions to applied linguistics, within the areas of pragmatics and sociolinguistics, include being founder, in 1977 (with Jacob L. Mey), and coeditor of the internationally recognized *Journal of Pragmatics*. He was thus a prime mover in the redefinition of linguistics as an interdisciplinary study of language as social practice, at a time when linguistics was being strongly influenced by mentalism and transformational grammar. Haberland's earlier research also inquired into the role of language in what was later to be known as information technology, computer linguistics, and "man-machine" communication (www.ruc.dk/~hartmut/). Later work focuses on the relationship between languages in multilingual societies and the role of language in interactive speech communication, as reflected in phenomena such as language alternation and language choice. His research interests also comprise language policy, and he is a well-known participant in the Danish language debate concerning the relationship between Danish and English as an international language. He is a founding member of the international research center CALPIU (Cultural and Linguistic Practices in the International University), which was first conceived at Roskilde University in 2003 (www.calpiu.dk).

Haberland was born in Hanover, Germany, in 1948. He studied German Language and Literature, General Linguistics and Philosophy in (West) Berlin and Stuttgart. He wrote his MA thesis within the area of Computational and Algebraic Linguistics in 1971. Since 1974 he has been living and working in Denmark, becoming a Danish citizen in 2005, his place of employment being Roskilde University. His past international experience, besides periods of employment at the Freie Universität in Berlin and the University of Düsseldorf (Germany), includes teaching at Copenhagen University (Denmark) and being an exchange professor at the University of Athens (Greece) and a visiting scholar in Japan (Dokkyo University, Saitama Province, 1995) and China (Beijing University of Foreign Studies, 1996). He taught at the Guangzhou Summer School of Pragmatics, China (2006), and carried out research-related work in Osaka (Kansai University), Japan, and the Hong Kong Institute of Education (2009), where Haberland is a Senior Research Fellow (External) of RCLEAMS (Research Center into Language Education and Acquisition in Multilingual Societies). More information is available online (www.ied.edu.hk/rcleams/).

The first widely known work (co-)authored by Haberland was a textbook, *Soziologie + Linguistik. Die schlechte Aufhebung sozialer Ungleichheit durch Sprache* (Hager, Haberland, & Paris, 1973), used at a number of universities in Europe for several years. The *Journal of Pragmatics* was founded by Haberland and Jacob Mey in 1977. In the editorial of the first issue, the authors defined pragmatics, not as an aspect or branch of linguistics, but as *a way of doing linguistics* (Haberland & Mey, 1977). There was thus no need for the classic distinction between "pure" and "applied" linguistics. Linguists were not to describe an abstract language "competence" but a concrete language "performance," which—just like any other social action—is a manifestation of social and societal conditions and practices. "The pragmatic question *par excellence* is therefore not: What does an utterance mean? But: How did this utterance come to be produced?" (p. 8), and the theoretical foundations of human socialization processes, including linguistic ones, are also the foundations of linguistics itself. As an extension of this line of thinking, Haberland's writings reflect

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

a general concern with the relationship between interaction and text, spoken and written language: to be analyzed, an utterance has to be decontextualized, thereby becoming a text (entextualization), which can be recontextualized (e.g., Haberland, 1994, 1999).

As another, related topic to which he has made several important contributions, Haberland—himself of German origin—is concerned with *language contact* as an aspect of social and ultimately cultural contact, obviously inspired both by his own encounter and experiences of many years with Danish language and society, and by his cross-cultural marriage (his wife is Irish). This has led to a preoccupation with the functions of language in face-to-face interaction, particularly the (sociolinguistic) question of “what makes people choose one language over another, if they have a choice?” His early works dealt with the languages of smaller European nations. Not surprisingly, when the awareness dawned that English was becoming the language of globalization and the dominant *lingua franca* of the world, Haberland became interested in the functions of English vis-à-vis other languages within societies or environments, or both, where English is not a native language (e.g., Haberland, 1989). In 1991 he coauthored (with three other linguists all of whom were non-native speakers of Danish) a provocative and much debated article on the danger of the Danish language being swallowed up piecemeal as its various functions are gradually taken over by English (Haberland, Henriksen, Phillipson, & Skutnabb-Kangas, 1991), thus co-initiating the debate on the influence of English in Denmark, which is still going on. English is often believed to be taking over various social “domains” (e.g., advertising or education), so that by the same token the local languages suffer “domain loss.” As a worst-case scenario, Denmark is thought liable to become a “diglossic” (Fishman, 1967) society, with English as the high-status language used in official and public domains, and Danish the low-status language of informal, private domains among family and friends. However, Haberland’s critical analyses of the “domain (loss)” concepts have pointed out that “domains,” if anything, are empirically based constructs whose objective existence can only be verified through sociolinguistic research; as mere a priori subjective notions, “domains” cannot in themselves be used as a basis for sociolinguistic investigation.

Haberland’s critique, on sociolinguistic grounds, of the popular explanation of how English is supposed to be supplanting other languages, domain by domain, should be seen in relation to his general concern with the global role of English, inspired by concepts such as “hegemony” (Gramsci, 1992–6) and “globalism” (Beck, 2005), see Haberland (2009). Within the framework of the CALPIU research center his research focuses on the complementary notion of “localization,” analyzing the role of the local language (*in casu*, Danish) in transnational student mobility—particularly transnational students’ need for and success in using local languages as languages of internationalization.

Haberland is coeditor (with Jacob Mey and Kerstin Fischer) of a new international journal, *Pragmatics and Society*, which appeared in the summer of 2010.

Halliday, M. A. K.

JONATHAN WEBSTER

For over half a century, Professor Michael Alexander Kirkwood (M. A. K.) Halliday (1925–) has been engaged in practicing “applied” linguistics. Approaching language from the vantage point of meaning and purpose, Halliday provides a theoretical framework, known as systemic functional linguistics (SFL), for dealing with questions about how and why we come to use language as we do for being and becoming who we are.

Born Easter Monday, April 13, 1925, in Leeds, Yorkshire, England, Michael Alexander Kirkwood Halliday grew up with two fascinations: one was China, the other language. In early 1942, Halliday volunteered for the national services’ foreign language training course, and succeeded in being selected to study Chinese. After spending a year serving overseas in India with the Chinese Intelligence Unit, doing counterintelligence work, he was pulled back to London to teach Chinese to new recruits. The need to explore pedagogical questions about Chinese became his first source of attraction to linguistics.

After leaving the army in 1947, Halliday decided to pursue his degree from the University of London externally in China. He enrolled as a student at Peking University, where he took classes in the Chinese Department. After completing his London degree, he worked in China for the Chinese Industrial Cooperatives for about six months before re-enrolling at Peking University. Luo Changpei, who Halliday had met during his earlier study there, took him on and started training him in historical linguistics and Sino-Tibetan studies. After about six months or so, however, it became clear to Luo that Halliday really wanted to work on Chinese dialects, so Luo arranged for Halliday to study under Wang Li at Lingnan University in Canton, about 1,500 miles to the south of Peking (Beijing).

Wang Li was conducting a phonetic survey of the widely differing varieties of Cantonese of the Pearl River Delta in southern China. Complementary to the ongoing phonetic survey, Halliday developed a grammar questionnaire to investigate not only the differences between Mandarin and Cantonese grammar but also how local dialects differed in their grammar from Cantonese.

Both Luo Changpei and Wang Li influenced the development of Halliday’s thinking, as evidenced by his paper “A Systematic Interpretation of Peking Syllables” (1992/2006), in which Halliday combined traditional Chinese phonology, as interpreted by Luo and Wang, with prosodic phonology as developed by Firth.

In 1956, one year after Professor Halliday completed his PhD at Cambridge, but three years before the subsequent publication of his PhD dissertation “The Language of the Chinese ‘Secret History of the Mongols’” (1959/2006), his paper “Grammatical Categories in Modern Chinese” was published in the *Transactions of the Philological Society* (1956/2006). In this paper he put forward a scheme of grammatical categories for the description of “Modern Pekingese formal colloquial,” or, as he described it, “the type of Chinese which a foreigner learns” (Halliday, 1956/2006, p. 210). The textual basis for this description came from a small corpus of spoken material, which he recorded in Peking and elsewhere.

While at Cambridge, Halliday became increasingly committed to general linguistics and especially to working with colleagues in the Linguistics Group of the British Communist Party. Although Firth was at the other end of the political spectrum, Halliday found considerable common ground between the Cambridge Linguistics Group’s thinking about

language and Firth's emphasis on the social nature of language, his central concern with meaning, his integration of the paradigmatic and syntagmatic modes of order, his sense of multiple patterning in language, his requirement of flexibility, and his clear distinction between general (theoretical) and particular (descriptive) categories.

Halliday also took part in the activities of the Cambridge Language Research Unit (CLRU), which was founded by Margaret Masterman. Whereas computer specialists saw machine translation as essentially an engineering problem, the CLRU instead considered it to be primarily a linguistic problem, requiring powerful theoretical tools for analyzing and synthesizing text. In the course of their discussions on the principles for representing linguistic structure, Halliday recalls putting forward his arguments for formalizing paradigmatic relations. However, as he recalls, "I did not know how to do it—and I totally failed to persuade anyone else of this!" (Halliday, 1993/2005a, p. 138). Since then, however, he has made significant progress toward advancing our knowledge of how one can indeed "model language paradigmatically: that is, as choice, with the system network as organizing concept" (Halliday, 1995/2005, p. 208).

In 1960, some two years after taking up the position of lecturer in general linguistics at Edinburgh, Halliday completed "Categories of the Theory of Grammar" (1961/2002), which proved foundational in the development of SFL. In 1963 he moved back to London, where as director of the Communication Research Centre at University College, he approached the Nuffield Foundation with a project for working on the grammar of English from an educational standpoint, with a view to curriculum development at primary and secondary level. The outcome was the Nuffield (later Schools Council) Programme in Linguistics and English Teaching, with a project team composed of primary school, secondary school, and university teachers. The materials developed through this collaborative effort included *Break-through to Literacy*, *Language in Use*, and, indirectly, *Language and Communication*.

Also in the 1960s, Halliday produced a phonological description for English intonation, which was based on his study of recorded texts of casual conversation among educated speakers of British English, supplemented by his own observations of naturally occurring speech, including his own. He analyzed intonation as a complex of three phonological systems, tonality, tonicity, and tone, these being interdependent with rhythm. Halliday also noted how the pitch contour of speech figures prominently in the exchange of information, foregrounding new information from that which is otherwise recoverable from the discourse and its context of situation. (See Halliday, 1963a/2005, 1963b/2005, 1967, 1985/2005.)

In the 1970s, prompted by his experience of working with teachers of English as a mother tongue and their questions about how children develop their ability to use language, Professor Halliday conducted an intensive study as a participant observer of his own son's developing linguistic ability from 9 months to 2½ years of age. The methodology was simple—using notebook and pencil to record Nigel's utterances. The data proved rich, providing a wealth of insight into how a child learns how to mean. Building on the work of Basil Bernstein, Halliday proposed a set of seven functions, the first six serving as the basis of interpreting the language of very young children: (a) instrumental, (b) regulatory, (c) interactional, (d) personal, (e) heuristic, (f) imaginative, and (g) informative. Through studying Nigel's language development, Halliday aimed to test his hypothesis that, in the transition to adult speech, these functions would appear, approximately in the order listed (see Halliday, 1975/2003).

In early 1976 Halliday moved to the University of Sydney as foundation professor of linguistics, and served as head of the department for its first 10 years. In 1979 he was elected a fellow of the Australian Academy of the Humanities, and in 1989 he became a corresponding member of the British Academy. He retired as emeritus professor from the University of Sydney at the end of 1987.

In the early 1990s, Halliday spent some time working with the COBUILD project at the University of Birmingham. It was there that he collaborated with Zoe James in a study of the systems of polarity and primary tense in the COBUILD corpus, and whose findings are reported on in "A Quantitative Study of Polarity and Primary Tense in the English Finite Clause" (1993/2005b). In 2002, he became the inaugural recipient of the AILA gold medal award for exemplary scholarship in the field of applied linguistics. He is currently advisor to The Halliday Centre for Intelligent Applications of Language Studies (City University of Hong Kong), which bears his name.

Perhaps because Halliday was a language teacher turned linguist his perspective has always been grounded in how we use language, and his goal has been to achieve an "applicable" theory leading to an understanding of the enabling power of language. His work has been of interest to educators, computer scientists, and practitioners in various professional fields. What comes across in Halliday's writings is a man with a great social conscience and strong convictions. While he makes no exaggerated claims about being able to radically transform language and society, he nevertheless sees the contribution linguists can make through achieving a better understanding of the power and potential of language for doing both good and bad.

This biography of M. A. K. Halliday is adapted from "M. A. K. Halliday: The Early Years, 1925–1970" (Webster, 2005), which was compiled from two sources: a previously unpublished interview conducted with Professor Halliday in 1987 by Gunther Kress, Jim Martin, and Ruqaiya Hasan; and "M. A. K. Halliday" by Keith Brown and Vivien Law (2002).

Hamp-Lyons, Liz

DEBORAH CRUSAN AND ALAN DAVIES

The work of Liz Hamp-Lyons (1946–) in applied linguistics, particularly in the area of second language writing and second language writing assessment, continues to have an impact on the field. In addition to these foci, she has made major contributions in the areas of teacher preparation, English for academic purposes, the assessment of speaking and listening, school-based assessment, large-scale testing, and test development. An international scholar, she has been one of the first second language writing assessment researchers to be recognized by and make inroads into the L1 composition world.

Education

As a young woman in England, Hamp-Lyons earned a Certificate of Education from the University of Leicester and began a career as a teacher. In 1976, she received an Advanced Diploma in English Language Teaching (ELT) from the University of Exeter, followed in 1978 by an MA in Language Education also from Exeter. She received her PhD in Applied Linguistics from the University of Edinburgh in 1986, focusing on writing assessment for her dissertation.

Academic Appointments

After a stint in Malaysia as an EFL teacher, Hamp-Lyons moved to the University of Edinburgh and a position with the Institute for Applied Language Studies (IALS). IALS had been charged with a major validation study of the English Language Testing Service (ELTS) test, launched a few years earlier by the British Council. Because of its unique English for specific purposes (ESP) construct, the test remained contentious in theory and cumbersome in practice. Hamp-Lyons pursued the validation, developing a special interest in the assessment of writing, which was central to the ELTS definition of specific purposes. That interest in writing assessment became the topic of her doctoral studies and remains as one of her main research interests.

In 1986, Hamp-Lyons took a position in the United States at the University of Michigan, Ann Arbor. At Michigan, she wore two hats: she worked in language testing at the English Language Institute (ELI) and served as associate director of the English Composition Board, at that time one of the premier composition programs in the United States. In that position, she managed the development of the writing assessment used to place all first year students into composition classes at the university, a monumental task. Because of her dual appointment at Michigan, she was able to bring together her rich experience in English as a foreign language, her growing interest in writing, and her skills in language testing. After moving from Michigan, Hamp-Lyons served as director for research in Applied Language Studies and coordinator of the MA in Applied Linguistics the University of Colorado, Denver, from 1990 to 1996.

In 1996, Hamp-Lyons moved to Hong Kong Polytechnic University (PolyU) as chair professor of English and head of the Department of English. In 1998 at PolyU, in addition

to her other positions, she became director of the Asian Centre for Language Assessment Research, an important juncture for researchers from the Chinese mainland where English learning, teaching, and assessment were growing very fast. Because of its primary focus on language rather than literature, the English department was a very suitable environment for Hamp-Lyons's work. Thanks to her predecessor, funding had been secured for a new English-language proficiency test, so Hamp-Lyons, with the help of Tom Lumley and Sari Luoma, developed the Graduate Skills Language Proficiency Assessment (GSLPA) to assess the English proficiency of Hong Kong university students at graduation. This special purpose test, making use of varieties of English native to Hong Kong, both in terms of accent and in terms of discourse patterns, was very much ahead of its time and should have been championed by proponents of World Englishes. Although the test still exists, it has fallen victim to political infighting among Hong Kong universities and to unease in official circles about the prospect of moving away from tests such as IELTS and TOEFL.

For nearly a decade, Hamp-Lyons concentrated on applied linguistics developments in Hong Kong. Then for a period of one year, she was at the University of Melbourne, Australia, where she acted as director of the Language Testing Research Centre and honorary professorial fellow in the School of Languages. Currently, she holds honorary appointments as special professor in English Language Education at the University of Nottingham, England, guest professor at Shanghai Jiaotong University in China, and honorary faculty of education professor at the University of Hong Kong and takes part in research activities and supervision, consulting, conducting funded research projects, and honorary professorial activities.

Journal Articles, Book Chapters, and Journal Editing

Liz Hamp-Lyons is widely published in the field of applied linguistics and TESOL. Her articles appear in journals such as *Annual Review of Applied Linguistics*, *Applied Linguistics*, *Assessing Writing*, *College Composition and Communication*, *College ESL*, *English for Specific Purposes*, *English Teaching: Korea Association of Teachers of English*, *ESP Malaysia*, *Higher Education Review*, *The International Journal of Interdisciplinary Social Sciences*, *Journal of Second Language Writing*, *Language Learning*, *Language Testing*, *Melbourne Papers in Language Testing*, *Modern Language Journal*, *Open Learning*, *Prospect: Journal of Australian TESOL*, *RELJ Journal*, *System*, *TESOL Quarterly*, and *World Englishes*. She has published numerous book chapters with Boynton-Cook, Cambridge University Press, Gunther Narr, Lawrence Erlbaum, MLA, NCTE, Routledge, Sage, Springer, and TESOL. She is the founding editor of the *Journal of English for Academic Purposes* and has coedited that journal with Ken Hyland since 2001. Also since 2001, she has been the editor of *Assessing Writing*. She served as coeditor (with Tom Lumley) of a special issue of *Language Testing* (Vol. 18, No. 2) on *Assessing Languages for Specific Purposes*, and in 1999 she served as editor of an endowed supplementary issue of *English for Specific Purposes*. From 1993 to 1998, she served as coeditor of *English for Specific Purposes: An International Journal*. She is a current member of the editorial boards of *Asia-Pacific Journal of Language in Education*, *English for Specific Purposes*, *Journal of Second Language Writing*, *Language Assessment Quarterly*, and *Writing & Pedagogy*. She is also a consulting reader for a wide range of journals. Through her editorial work, she has mentored scholars, both veterans and those new to the field, and brought them into international conversations about issues such as English-language teaching, second language writing, and the assessment of writing.

Books

Hamp-Lyons has authored several books that have been quite influential, especially in the field of second language writing and writing assessment. With Ben Heasley (1987), she wrote *Study Writing* (currently in its second edition), a text for intermediate to advanced writers who wish to develop their skills in academic writing in English. Her Hampton Press book with Bill Condon (2000), *Assessing the Portfolio: Principles for Practice, Theory, and Research*, is an exploration of the theoretical foundations of portfolio assessment, an in-depth discussion of types of portfolios, when they should be used, how they should be used, and how their use affects writing programs. Bringing together her testing and writing interests, she wrote a student manual on the Test of English as a Foreign Language, *Preparing for the TOEFL Test of Written English* (1989). Her edited collection, *Assessing Second Language Writing in Academic Contexts* (1991), is one of the first volumes to push for the direct assessment of writing, a cutting-edge notion at the time of publication.

Research Contributions

Over the years, Professor Hamp-Lyons has received very large grants to fund the many research projects in which she has been involved. In Hong Kong, she has explored the impact of high-stakes ESL assessment on secondary schools, curricular alignment in junior secondary English-language teaching, and many other aspects of testing and its impact on schools. Throughout her career, she has involved her students in her research. Other important research projects include countless research student support grants to study such issues as testing reading for specific purposes, test preparation, the role of critical thinking in learning to write, washback studies, and progress assessment in distance education. Further, she has been an advocate for fairness in testing, supporting the creation of the International Language Testing Association's Code of Ethics, an important step for language testers.

Hamp-Lyons has presented the results of her research in places such as Australia, Canada, China, Germany, India, and the United States, has supervised the work of countless doctoral students, and has been external examiner for students in the United States, Australia, Hong Kong, and British Columbia. She has served as external reviewer for tenure and promotion cases around the world. To say that Liz Hamp-Lyons has had a tremendous impact on the field of applied linguistics, second language writing, and second language writing assessment is an understatement. She is a great teacher-researcher with particular understanding of and empathy with language teachers. Her far-reaching influence will be felt for a long time.

Hasan, Ruqaiya

ANNABELLE LUKIN AND GEOFF WILLIAMS

For the field of applied linguistics, language must first and foremost be considered as it functions in the exchange of meanings. This foregrounding of the meaning-making potential—indeed, *raison d'être*—of language, coupled with an assiduous interrogation of what follows from taking this position, characterizes the over 50-year career in linguistics of Ruqaiya Hasan (1931–). She has built on a theory and method which follows from principles about language–meaning–reality connections developed by scholars such as Saussure, Whorf, and Firth. In seeing language as a “shaper of reality for those who use it,” she has urged linguists to “abandon the externalist view that meaning is something external to language.” She argues instead for a linguistic model

that is capable of doing two seemingly disparate things at once: first, we need to show that meanings are the very artifact of language and so are internal to it; and secondly, that these linguistically created meanings nonetheless pertain to our experience of the world around us and inside us. (Hasan, 2009 p. 136)

Hasan's first academic position (in 1954) was as lecturer at a training college for teachers of the Deaf in Lahore, Pakistan. Forty years later she retired as emeritus professor from the Department of Linguistics at Macquarie University in Sydney, where she had worked continuously since arriving in Australia in 1976. Her undergraduate studies (in English Literature, Education, History) were conducted at the University of Allahabad, which she followed with an MA in English Literature at the University of the Punjab. In the decade and a half she lived in the UK, she completed a postgraduate diploma in applied linguistics, and a PhD (both taken at the University of Edinburgh), and then held three research fellow positions funded under grants from the Nuffield Foundation. The last of these was in the Sociological Research Unit, where she worked with Basil Bernstein, directing the project on sociolinguistic aspects of children's stories. While at Macquarie, she conducted research over a 10-year period into the role of everyday talk between mothers and children in establishing a child's orientation to modes of learning, which formed the basis of her research on semantic variation (Hasan, 2009). She also investigated the structure of reasoning in everyday talk.

Hasan's work draws on Michael Halliday's systemic functional theory, a linguistic framework in which meaning mediates the relationship between linguistic form and the “eco-social environment.” In her words, “I have a feeling there is continuity from the living of life right down to the morpheme” (Hasan, 1996, p. 1). She has argued the case for why Halliday's theory is most suited to explaining the pervasiveness, elasticity, and power of language. Halliday has recently coined the term “applicable linguistics” to mean a linguistic theory capable of being drawn on for the description of any kind of linguistic activity, indeed a theory itself shaped and theorized under the pressures of accounting for the breathtaking diversity of human discourse.

Hasan has extended the applicability of Halliday's model with the development of several powerful descriptive tools or frameworks. One is her proposal regarding “generic structure potential” (Hasan, 1985a), both a theoretical and a methodological statement on the analysis of text structure and its relation to context of situation. It displays the character

of all Hasan's tool-like proposals in that it is situated within a full account of the relation of the relevant terms to a general linguistic theory. Hasan shows how text structure is a function of all aspects of the social context (in systemic functional theory, the aspects of field, tenor, and mode). She also relates text structure to texture, by showing how texture is the working out, for specific instances of social interaction, of the higher-order abstractions which give a text its shape as an instance of a register (see Halliday & Hasan, 1976; Hasan, 1984a, 1985a, 2011c).

Having shown, with Halliday, how one can produce a robust and systematic account of meaning, linguistic form, and social context, Hasan has also indicated how a meaning-oriented perspective on language can resolve another pseudo-dichotomy, that between mind and society: "human life as we know it is fashioned in the dialectic processes of both language and society; all meanings are social and all meanings are cognitive" (1993, p. 379). The first two volumes of her collected works (Hasan, 2005, 2009) show her nearly 40-year-long interest in bringing Halliday's linguistic theory into dialogue with both psychology and sociology. Hasan argues that it is a function of the "exotropic" quality of Halliday's theory that this dialogue is possible: "an exotropic theory is not confined within the bounds of its object of study. Rather it is cosmoramic, typically embedding its central problematic in a context, where the processes of its maintenance and change originate in its interaction with other universes of experience" (Hasan, 1999a, p. 51).

Her dialogue in these two volumes is, principally, with Vygotsky's work on semiotic mediation, with Bernstein's work on pedagogic discourse and the reproduction of class relations, and with Labov's arguments against "semantic variation," a concept in sociolinguistics for which he was responsible (e.g., Weiner & Labov, 1983). Using Vygotsky's and Bernstein's work, Hasan shows that

there is a logical relation between a subject's social positioning and the mental dispositions, habits of the mind, the orders of relevance which they bring to bear on whatever they encounter in their social life: there exists an ineluctable relation between one's social positioning, one's mental dispositions and one's relation to the distribution of labour in society. (2005, p. 152)

Contra Labov, Hasan's research provides robust empirical evidence, based on analysis of language use in natural social contexts, that semantic variation is undeniable. Hasan's findings validate Bernstein's "coding orientation theory," the idea that one's orientation to meaning in context varies, systematically, on the basis of one's social positioning.

Naturally, this research has had important implications for education. But Hasan has not engaged directly with the content of classroom practice, a "deliberate decision on my part" (2011a, p. xvi). She has concerned herself instead with learner identity, and with the way social issues impinge on the processes of education (Hasan, 2011a, p. xi). For Hasan, learner identity is formed in the process of everyday living (e.g., Hasan 1984b). Understanding the "fashions of speaking" (Whorf, 1956, pp. 158–9) that learners bring should be the foundation of any educational process. While decisions about content and instructional methods are obviously important, "none of these are likely to make any difference unless the learner can make sense of what he/she is receiving as discourse" (2011a, p. xiv).

All of this work has depended on the development of the notion of "relevant context" (see Hasan, 1980, 1999b, 2012). Applied linguistics can be said to define itself by the application of linguistic theories to contexts of human interaction. Hasan has developed, sharpened, and operationalized Halliday's notion of social context—borrowed originally from Malinowski, developed in the work of Firth, and ultimately brought within the scope of a linguistic model with Halliday. Hasan has shown that context is "a semiotic construct"; that the reason language is means to so many ends is that the ends were created by language itself.

Hasan's contribution is perhaps unique for the degree to which she has extended a general linguistic theory, at the same time that she has made profound inroads into the study of important aspects of society and culture. The diversity of contributions she has made to general linguistic theory is remarkable, and includes studies of lexis and lexico-grammar (e.g., Hasan, 1987; also 2011d), a description of the semantic unit of "message," studies in cohesion and coherence, a theory of text structure in relation to social context, and the development of a robust, theoretically delineated conception of context. The contexts of language use to which she has turned her formidable critical eye include the culture/systems of education, everyday talk in the formation of identity, language and ideology, pedagogy and verbal art (see Hasan, 1971, 1985b, also 2011e). On pedagogy, she coined the term "reflection literacy," defined as "literacy for educating to produce knowledge" (Hasan, 2011a, p. 199). This orientation to learning as a platform for students to become agents of knowledge production, rather than simply reproduction, goes back to the work on verbal art with which she began her academic career. Hasan produced a linguistic conception not just of the language of literature, but of the teaching of literature "to enable the learner to produce an independent reasoned 'reading' of some existing work in literature" (Hasan, 2011b). Her decision to take on the question of how to teach literature in these terms she describes as academically "the most important decision of my life" (Hasan, 2011b).

Hatch, Evelyn

HOSSEIN FARHADY

Evelyn Hatch (b. 1929) is Professor Emerita at UCLA Department of TESL/Applied Linguistics. She began her studies at UCLA in the 1960s, completing, in fairly rapid succession, a BA in political science, an MA in linguistics, and a PhD in education. This broad academic background reflects Hatch's diverse interests in her career in applied linguistics. In addition to being an exceptional teacher, Hatch has been a leader in several areas, especially in second language acquisition, research methods, and discourse analysis. Although it is truly difficult to do justice in writing about her services to the profession, the following touches the tip of the iceberg.

As a teacher and an administrator, Hatch had remarkable accomplishments. Before joining UCLA TESL (teaching English as a second language) department, Hatch had taught English in Egypt at the American University of Cairo (AUC) to Palestinian students, and ESP (English for specific purposes) classes to Cuban refugees who were her students at Mt. St. Mary's College. By the time she joined UCLA faculty in the mid-1960s, the TESL department at UCLA was cooperating with and directing many projects in universities and academic organizations around the world. Hatch worked on many of those projects—first in Peace Corps training of EFL (English as a foreign language) to teachers (and nurses) in Ethiopia, Nigeria, and in Central America. Then she joined the program for Navajo teachers during a summer course that promoted an ESP approach to courses such as electrical engineering. She later returned to Egypt to direct the UCLA team that helped establish the National Center for the Development of English Language Teaching (CDELT) at Ain Shams University, where she was awarded the Ain Shams Medal for service to English-language teaching on the occasion of the 10th anniversary of the CDELT. During her stay there from 1977 to 1982, she assisted the General Directorate for In-Service Training on numerous occasions, giving her access to schools and training programs all over the nation. She also served as team leader to evaluate the Integrated English Language Program in Egypt for the Ministry of Education.

In addition, Hatch has enjoyed a dynamic career both at home and abroad. She has worked with many distinguished scholars around the world. She was among the first educators to visit and participate in seminars in Moscow, Barnaul, Kiev, and the early programs in Hungary. Through TESOL (teaching English to speakers of other languages) Summer Institutes, the Summer Linguistics Institutes, Fulbright, and other organizations, she visited Morocco, Barcelona, Berne, Edinburgh, and major institutions in Australia and delivered invited plenary talks in many countries. Hatch also served in many programs and project evaluation activities. She gained skills in the area of evaluation through her own projects that had to be evaluated. She received grants from major funding agencies (Ford Foundation, USIS, AID, UCLA, etc.) that often brought outside experts to the projects. Observing them at work, she developed skills needed for evaluation. She frequently assisted the department in evaluating overseas projects, especially those in China.

Following the establishment of an annual English Language Teaching and Research Forum in Cairo with her students, Hatch founded the Second Language Research Forum (SLRF) at UCLA, the only major conference in the field organized entirely by graduate students. In the early years, hosting SLRF would rotate between the UCLA and USC

applied linguistics programs. Upon Hatch's retirement, past students and colleagues established the Evelyn Hatch Award for excellence in graduate students' research at UCLA in recognition both of her own influential research career and the encouragement she gave to all who worked with her.

As well as her remarkable achievements as a teacher and an administrator, Hatch has made even more significant contributions to several disciplines in applied linguistics and, in fact, has been a leader in areas such as second language acquisition, discourse analysis, and research methodology. During her PhD studies, she took a research position at Southwest Regional Laboratory (SWRL) working on child first language experiments (the topic of her PhD dissertation) and acquisition of reading skills. The models of research design and analyses employed in SWRL influenced her future work to a great extent. Working on these projects, she realized the overlap of cognitive, social, and linguistic factors in language learning and developed a multidimensional perspective on issues in applied linguistics. She strongly believed that many disciplines should be integrated in applied linguistics in order to find solutions to language-related issues. Two publications that perhaps best show this major theme of her work are Hatch, Shirai, and Fantuzzi (1990), and Hatch and Yoshitomi (1993).

When the UCLA certificate program was evolving into an MA program, Hatch began implementing her ideas by offering new courses. The initial certificate program included core courses in methodology, English grammar, contrastive analysis, and practice teaching. With her interest in second language acquisition that was ignited by Professor Werner Leopold, Hatch suggested that some elective courses in her areas of research be added to the program. The first course was in second language acquisition, and the outcome of teaching that course was the collection of readings for second language acquisition (SLA) published in 1978; it became, and remained, a main textbook for SLA classes for a long time.

In the 1970s, when research on second language acquisition expanded, researchers proposed different models to explain and account for the processes underlying SLA. Among many others, Hatch (1978a) suggested discourse analysis as a methodology for the study of SLA. According to this model, language learning evolves out of learning how to carry on conversations. In other words, syntactic structures develop from communicative interactions and most language acquisition processes are the result of conversational growth. Hatch enriched this model by connecting it to simplified input and claimed that appropriate simplified input "promotes communication, establishes an affective bond, and serves as an implicit teaching mode" (Hatch, 1979, p. 1). With the popularity of discourse studies in the field, Hatch offered a course on discourse analysis. The class materials were later published as a book on discourse analysis (Hatch, 1992), which was the winner of the Kenneth W. Mildenberger Prize awarded by the Modern Language Association.

Closely related to SLA and discourse analysis was the need to establish a better understanding of the psycholinguistic processes involved in SLA. To this end, Hatch offered a new course on psycholinguistics to capitalize on the cognitive aspects of language acquisition. Through the course, she emphasized the need for considering the overlapping dimensions of cognitive, social, and linguistic aspects of language acquisition processes. The materials for teaching this course resulted in the publication of a book on psycholinguistics (Hatch, 1983), which was awarded the American Library's Association award for best notification.

Both at CDELT and in the UCLA MA program, Hatch discovered that teachers and trainers needed special preparation in understanding and conducting solid research in applied linguistics. To fulfill this need, she offered a course on research methodology in applied linguistics and, in order to prepare course materials, she asked Hossein Farhady, then a PhD student, to work with her in writing a book for the course. Hatch and Farhady

(1982) was the first book in research methods to appear in applied linguistics, and had a great influence on the future of research in the field. Upon her return to AUC as a Distinguished Visiting Professor to teach and also to continue her work with CDELT, Hatch observed that both at CDELT and at UCLA, candidates had broadened their research horizons and implemented various research methods beyond what was introduced in Hatch and Farhady. To meet the emerging needs, she revised the book with another graduate student, Anne Lazaraton, and made an almost new book that included new developments in research methods and statistics (Hatch & Lazaraton, 1991), which is still used as a textbook of research methods in applied linguistics in many universities. Hatch (Hatch et al., 1990) held a position that is nowadays known as mixed method and process-oriented research by stating that research is a discovery process rather than a product to be published, that there is no a single answer to the questions, that answers interact, and that the interactions can lead to more interesting areas of research.

One of her admirable features was that Hatch always offered opportunities to her students in preparing the materials for various courses and then publishing them. Hatch/Farhady and Hatch/Lazaraton were just a couple of them. She also gave an opportunity to Cheryl Brown to work toward preparing materials for courses she was teaching at USC, Arizona State University, and the TESOL Summer Institute. One of the outcomes of this cooperation was a book called *Vocabulary, Semantics, and Language Education* (Hatch & Brown, 1995). Again, the Modern Language Association awarded it the Mildener Prize for that year.

Hatch no longer works, except as a teacher aid in Los Angeles area elementary classrooms where many, often most, are children who are becoming bilingual. She is still working as a docent at the Antelope Valley Indian Museum and helping with outreach programs to 3rd and 4th grade classrooms. And, of course, she is still writing letters of recommendation for her former students and colleagues, reading and evaluating articles for a few journals, and occasionally receiving research papers from avid applied linguists from around the world.

It is not easy to do justice to Evelyn's services to the field of applied linguistics. It is certain, however, for decades to come, the field of applied linguistics will remember and value Hatch's contribution to the field and will respect her for her outstanding accomplishments.

Health-Care, Medical, and Mental Health Interpreting

CLAUDIA V. ANGELELLI

Introduction

Health-care interpreting occurs between users and providers of health-care services (including mental health) who do not share the same language. It involves the transfer of verbal and nonverbal messages across languages in real time. The language of health-care providers is mainly the societal language(s) of the country where the medical encounter takes place and the other language is that of the migrant and the migrant's family, that is, members of linguistic minorities. Health-care interpreting serves the latter user group ensuring their access to health services. Both in urban and rural areas, when speakers of linguistic minorities seek access to health-care services, communication between them and health-care providers who speak the societal language is enabled by interpreters.

Health-care interpreting has unique features that distinguish it from other types of interpreting. Unlike conference interpreting that most frequently is done in one direction only, in a simultaneous mode, and with more prolonged segments of discourse, health-care interpreting is a bidirectional communicative activity, done in a consecutive mode, with shorter segments of discourse. Unlike court or legal interpreting which is adversarial, health-care interpreting is assumed to be a consensual activity. This means that all the participants, that is, the service user (also called the patient or client), the service provider (either the health-care professional or the administrator of the organization), and the interpreter share the same goal: successful diagnosis and therapy.

Health-care interpreting should not be confused with medical translation. While medical translation involves the communication of a written message into another language in written form and a certain period of time is allocated for the task, health-care interpreting involves the communication of oral or signed messages in real time. In addition to the difference between the written and oral forms and the time constraints, health-care interpreting conceptualizes communication as the result of human interaction. As such, it means brokering messages that are formed not only by words but also by body language, facial expressions, and gestures during an interpreted communicative event.

In the USA, the end of the 20th century and the beginning of the 21st witnessed important changes affecting health-care delivery to limited-English-proficient patients. As part of the nation's effort in the 1960s to protect the civil rights of minorities, Title VI of the Civil Rights Act of 1964 and recent federal initiatives require health-care organizations that receive federal funding to provide meaningful language access for limited-English-proficient patients. Even when other legislation also supports these requirements, minimal progress has been made within most health-care systems to achieve the intent of these regulations. From attempts to match patients' and providers' native language, to hiring face-to-face or remote professionals, or ad hoc interpreters, or resorting to family or community members as temporary language facilitators, health-care organizations continue to explore creative solutions to bridge the linguistic barrier between providers seeking to assist patients and patients seeking medical assistance (Metzger, 1999; Angelelli, 2004a; Ticca, 2007).

Settings

Health-care interpreting generally occurs in mainly health-care (governmental and non-governmental) settings such as hospitals, doctors' offices, community clinics, and some types of social-services offices. Unlike conference, court, or legal interpreting which generally occur in front of an audience, and interactions are public, health-care interpreting interactions are private. In these settings interpreters work face-to-face, over the telephone or via a teleconference. Health-care interpreters, capable of processing and conveying information in two languages, often work under conditions of critical and extreme pressure in which the patient's life may be at stake.

Recent technological developments coupled with high demands for service and the low supply of educated professionals willing to work under the current state of affairs (low salary, limited conditions of workplace) have transformed the job of health-care interpreters significantly. Nowadays, rather than brokering communication during traditional face-to-face encounters and observing healthy conditions in their workload (e.g., taking breaks every 30 minutes of uninterrupted work), health-care interpreters perform their roles via the speakerphone, regular teleconferencing, or videoconferencing, working for extended periods of time without breaks (Meyer, 2001; Angelelli, 2004a, 2007). These changes in the workload and settings complicate the task at hand even more.

Parties Involved

In a health-care-interpreted communicative event there are three parties: the health-care provider, the patient, and the interpreter. Because the need for interpreters in medical settings has grown exponentially, the supply of qualified interpreters to meet that need is not sufficient. In the absence of a qualified interpreter, speakers of minority languages who need to seek health care resort to what is available to them. Sometimes the role of the interpreter is played by bilingual-service providers (e.g., a laboratory technician), bilingual janitors, friends, family members, or members of the community who are proficient in English. These bilingual speakers who may or may not have had experience in interpreting are asked to step in and to help broker communication. They do it with various degrees of success based on their expertise and experience or lack thereof. This can lead to serious consequences that undermine equal access to services. It is generally agreed that, if available, a professional interpreter is always the best choice.

Internationally, perhaps the most controversial issue around professional versus non-professional or ad hoc interpreters is the use of children, who may be friends or family members of the patient, as the patient's interpreter.

End users (patients or clients) of health-care interpreting are generally migrants that settle in the new country looking for better opportunities. Health-care professionals speak societal language and frequently use *medicalese*. In health-care encounters, there are salient differences in social factors, such as level of education, socioeconomic status, and so on, between providers and patients. Health-care interpreting generally occurs across a wide range of social factors (gender, ethnicity, socioeconomic class, education, age, and nationality) and gulfs of cultural differences. Health-care interpreting may also occur where differences in socioeconomic status between providers speaking the societal language and end users are not that significant. These are cases of patients who are temporarily visiting an area to seek more affordable medical treatment in other countries where they do not speak the language (e.g., Germans in Korea or Americans in Mexico). Finally end users may also be tourists who may need medical assistance during their stay or seniors who decide to retire to a foreign country/community (e.g., the British who retire to Spain).

Role

A health-care interpreter is an individual capable of processing and conveying information in two languages, often under conditions of critical and extreme pressure. Their role is multifaceted and complex. It is not limited to encoding and decoding messages into a different linguistic code or the exercise of cognitive skills (content selection, memory, anticipation, split attention). It also entails managing the bilingual dialogue, controlling the traffic of communication, monitoring the interaction, recognizing sources of misunderstandings and addressing them, as well as displaying empathy. All of these, coupled with the fact that interpreters may walk into a case without any preparation (Meyer, 2001), add to the intricacy of the role. In the course of their jobs, medical interpreters comprehend and produce language of various degrees of complexity. They alternate between target and source languages, rural and urban varieties, and they work with speakers whose level of education ranges from second grade to graduate school. This means that interpreters navigate speech communities in which there are asymmetrical relations between speakers of more and less dominant societal groups. In addition to the social factors of each of the parties for whom they work, interpreters bring their own self and their own personal set of social factors to the interaction, adding to the difficulty. As the interaction does not happen in a social vacuum, but rather it occurs within one institution that is permeable to the mandates of society, various layers of institutional and societal influences surround the interpreted communicative event. This adds to its complexity and the complexity of the interpreter's role (Angelelli, 2004b).

Since the supply of professional or qualified interpreters cannot begin to match the demand for service, sometimes institutions rely on telephone interpreting services to facilitate communication with patients and families. This resource may be especially helpful for speakers of less commonly spoken languages. In discussing the issue of volunteers who play the role of the interpreter, scholars have different views when it comes to accepting less qualified (or untrained) individuals to do the job. Some believe that even when volunteers may not be the best option it would be unthinkable not to allow volunteers such as family members and friends to play that role. Hospitals are yet not equipped to face the demand for interpreting services. This is both due to the cost of the services as well as to the short supply of qualified interpreters (Garcia, Roy, Okada, Perkins, & Wiebe, 2004; Meyer, 2007, in Ticca, 2007). Banning volunteers may result in limiting access to health-care on the part of linguistic minorities. In addition some researchers do not consider family members interpreting for their loved ones as necessarily problematic (Edwards, Temple, & Alexander, 2005; Green, Free, Bhavnani, & Newman, 2005). Others argue that confidentiality may be jeopardized when family or friends play the role of the interpreter (Fiola, 2003) or that it may be emotionally distressing for them in the case of serious medical problems (Jacobs, Kroll, Green, & David 1995). When language assistance is needed and professional interpreters are not available, ad hoc interpreters are called but this is problematic (Garcia et al., 2004).

Research in Health-Care Interpreting

Research in health-care interpreting comes from different fields and is not abundant. There has been little cross-fertilization between research on cross-cultural communication conducted in applied linguistics (specifically in interpreting studies or communication in the workplace), sociology, or communication and relevant research conducted in the medical field (Angelelli, 2008). Research performed in the medical field, generally of a quantitative nature, tends to focus mostly on error and compliance and on the economic aspect of

providing language services. Results of medical studies have shown that in a health-care setting, the lack of a common language and culture between patients and providers is a barrier to effective communication. In addition this barrier decreases the quality and accessibility of health care. If language barriers are not overcome, adverse health consequences including poor medical care, misdiagnosis, inappropriate medication and hospitalization may occur. These communication issues are also associated with a higher rate of resource utilization for diagnostic studies, as well as with decreasing understanding in patients of their disease processes, which has a subsequent impact on their compliance with treatment and follow up care (Bonacruz Kazzi & Cooper, 2003).

Results of studies from interpreting and applied linguistics, sociology and communication, resorting both to qualitative and quantitative methods, tend to problematize the complexities of the crosslinguistic interaction, as well as its power differentials, while focusing on the role of the interpreter and of the language. From quantitatively assessing interpreters' perceptions and beliefs in their roles, to qualitatively observing health-care interpreters as they enact their roles and interviewing them as they describe their interactions in their own words, studies discuss the extent to which interpreters play an active role in the interaction and the consequences of such participation (Angelelli, 2007). Research has also discussed the risks of not using qualified interpreters (Meyer, 2001; Fiola, 2003; Garcia et al., 2004).

Teaching and Learning

The teaching and learning of health-care interpreting involves the development of skills in at least six different areas. These are: cognitive-processing, interpersonal, linguistics, professional, setting-specific, and sociocultural (Angelelli, 2006). Most of the short courses commercially available that offer training in health-care interpreting generally devote time to terminology or the ethics of the profession and they may not even discuss information-processing skills. More elaborate programs focus on information-processing skills and linguistic ones, and may not dive into the specifics of the medical setting and the interpersonal role of the health-care interpreter.

Since interpreting entered academia to meet a pragmatic need (rather than to become an object of study), research questions about practice, the various aspects of the medical settings, and the practitioners, which are essential to understand the underlying complexities of the interpreted communicative event, were deferred to the market need of practitioners. Logistical questions focused on conducting training took priority over questions that were designed to understand what a well-rounded education of interpreters may look like. For example, based on educators' personal experience and opinions rather than on research, many programs that teach health-care interpreting are reduced to teaching terminology related to the field. As a result, health-care interpreters have a range of educational backgrounds with some holding a master's degree in medical interpreting and others having received no education in the field (Angelelli, 2004a, 2006). The truth is that there are limited educational opportunities for health-care interpreters to pursue. For staff interpreters, training occurs at the workplace. As Garcia et al. (2004) suggest, hospital-trained interpreters are found to be a valuable and much-needed resource to facilitate communication with limited-English-proficient patients and families and as noted by Flores et al. (2003) interpreting errors that have potential clinical consequences occur more frequently with ad hoc interpreters than with hospital-trained interpreters.

Theory and research on health-care interpreting are generally not part of the hospital in-house training program and important findings are ignored by practitioners. By bringing theory and research to bear in the education of health-care interpreters, students become

aware of the role they may or may not choose to play and of the power they have as interpreters. They learn how to use their interpersonal skills effectively, and to understand the responsibilities and duties that arise from their tasks. Students need to learn that health-care interpreters, like interpreters in general, are co-participants who share responsibility for effective communication. They also need to reflect on the consequences of their participation.

Testing/Certification

To date there is no national certification for health-care interpreting. Therefore, there is no standard method of assessing linguistic and interpreting skills of those employees if or when health-care organizations wish to provide meaningful language access to linguistic minorities by hiring bilingual staff to interpret.

Currently there are no universally agreed rules for health-care interpreters working in different types of medical encounters. This makes it difficult to define the construct of health interpreting skills or competencies to be tested. Therefore, interpreters working over the phone, via a teleconference, or face-to-face are not assessed on how they react to the different impacts that each of these types of interactions place on them, on their role, and so on.

For staff interpreters, testing is generally done by an in-house test created by the organization for which the interpreter works and it is limited to some exercises on memory or terminology, for example. When testing is more comprehensive, whether it is done in-house or by interpreting agencies or organizations, it also tends to focus on areas of information processing (memory, analytical skills), language proficiency, and specific medical terminology. Although the measurement of cognitive and linguistic skills, as well as specific terminology, is essential while testing interpreters, it provides only a partial view (Angelelli, 2006). The role that interpreters play during a health-care interaction (i.e., the display of the interpreter's agency, human interaction, knowledge of limits, etc.) is not assessed. This role, however, is crucial to the successful and responsible performance of interpreters. In many cases, interpreters are not even aware of the agency they possess, nor are they always conscious of the consequences of exercising it (Angelelli, 2004b).

As we know from the literature (Metzger, 1999; Angelelli, 2004a) other skills (such as interpersonal or social ones) are as crucial as cognitive and linguistic skills, but are seldom measured. This means that constructs such as neutrality, objectivity, and invisibility are prescribed by codes of ethics and assumed, but not tested. Nor is there a mechanism for enforcing codes of ethics or standards of practice for either interpreters or agencies/organizations hiring interpreters. This knowledge is also not tested.

The Professionalization of Health-Care Interpreting

The evolution of health-care interpreting as a profession can best be illustrated by a continuum that encompasses indifference toward communication issues, or the denial thereof, dependence on ad hoc interpreters, generic language services, and full-fledged interpreting services. Health-care interpreting is striving to establish itself as a profession. It continues, however, to be perceived as a less prestigious variety of interpreting, practiced mostly by ad hoc interpreters. This perception is also evident in the fees that health-care interpreters are able to demand. They are significantly lower than those received by conference and court interpreters. Clearly, this perception of a less prestigious practice is not due to a lack of complexity within the health-care interpreting field.

A characteristic of a profession is the access to a body of knowledge shared by its members. This corpus is composed of theories and research that, in turn, inform pedagogy and practice. When discussing professionalism, the issue of education—which lies at the basis of any profession—has been almost overlooked and has always been subordinated to economic priorities and market needs. Logistical questions directed to conducting training take priority over questions that are designed to understand what a well-rounded education of interpreters may look like and how it would account for the differences in settings where interpreters work. This leaves practitioners who care about their work in a state of confusion as to who is qualified to practice and who is not, what makes a professional interpreter or what experience or training are necessary (Angelelli, 2006). Professional associations have yet to grapple with these issues.

Ethics

There are various codes of ethics and standards of practice in countries such as Canada, Spain, and Australia. In the USA there are codes both at state and national level (e.g., California Healthcare Interpreting Association and National Council for Interpreting in Healthcare respectively). In general codes for health-care interpreting are not significantly different from codes for conference or court interpreters. Most of them discuss faithfulness to the meaning of the original message, accuracy and completion in the interpreted rendition (i.e., interpreters should not add or omit anything), and confidentiality. Even when health-care interpreting differs significantly from other types (e.g., court or conference), only a few codes explicitly mention interpreter behavior that goes beyond the conduit encoder-decoder, and to which interpreters sometimes resort, that may include advocating for the patient.

Some health-care interpreters see the provision of language assistance as a human right. Some hospitals ask interpreters to perform duties outside interpreting (e.g., accompanying patients to the pharmacy, helping to push a wheelchair). Therefore interpreters have to reconcile ethical guidelines of professional associations with workplace requirements. In some cases interpreters may not observe prescriptive guidelines (e.g., related to confidentiality or faithfulness) if they felt there was a serious risk to the health or life of the patient. For example, if a mental health patient told an interpreter some confidential information (e.g., former attempts of suicide) that is relevant to the interpreted encounter, the interpreter may decide to step out of the prescribed role, breach confidentiality and inform or explain the situation to the provider. Another example illustrates the tension between impartiality as an ethical principle of professional associations' standards of practice or codes and the policies of interpreters' employers and agencies: in many health-care institutions and interpreting agencies, interpreters are required to play the role of an advocate or a social worker.

Heath, Shirley Brice

JENNIFER MCCREIGHT, ROBERTA GARDNER,
JAYE THIEL, AND JOBETH ALLEN

Shirley Brice Heath (1939–), a linguistic anthropologist, works at the macro and micro levels to study language in political and sociocultural contexts. The largest body of her ethnographic work examines the ways that children and young adults develop language and social practices in families, friendship groups, and community youth organizations. She received a BA (1962) from Lynchburg College, an MA (1964) from Ball State University, and a PhD (1970) from Columbia University where she specialized in Cultural Anthropology and Linguistics, Comparative Education, and Latin American Studies. She holds the Margery Bailey Professorship in English and Dramatic Literature and a Professorship in Linguistics (Emerita) at Stanford University, where she taught from 1980 to 2003. She was professor at large, Brown University (2003–10) and has taught at the University of Pennsylvania; Kings College, University of London; University of Witwatersrand, Johannesburg, South Africa; University of Washington; and the University of Colorado. Her awards include a MacArthur Fellowship, the Grawemeyer Award in Education (with Milbrey McLaughlin), the George & Louise Spindler Award in Educational Anthropology, the Distinguished Scholarship and Service Award, American Association for Applied Linguistics, and the Distinguished Educator Award from the American Education Research Association. A prominent voice in applied linguistics internationally, Heath has conducted research in Mexico, Guatemala, South Africa, the United States, England, Germany, Australia, and Sweden.

Heath's earliest work focused on language policies in Mexico (1972) and the United States (1981). In the 1970s, she began ethnographic fieldwork with families in textile mill communities in the southeastern US Piedmont region. She studied 300 families in White, working-class Roadville and nearby Black, working-class Trackton, reporting this decade of work in her ethnography *Ways With Words* (1983/1996; henceforth *WWW*) which remains a cornerstone in applied linguistics, showing the relationship between micro- and macro-level discourse, and the effects of children's early language and literacy experiences on their lives inside and outside of school. Employing Hymes's "ethnography of communication," with its focus on connections among language, community, and identity, Heath studied discourse in these communities as shared events, embedded in social practices. Heath (1982) developed the notion of literacy events, an interaction around a piece of writing, as a tool for examining various forms and functions of oral and written language. She documented very different "ways with words," both in ideology and use, by linking shared language practices to larger societal discourses. She found that the rich language and literacy skills of children in Trackton were not initially valued in school. Questions in school bore little resemblance to parental interrogatives; Trackton parents did not ask "known-answer" questions, so their children were often confused when teachers requested them. School texts and tests called for literal answers; Trackton children were skilled at metaphor, imaginative stories, and arguing claims. Children from Roadville did well in primary grades, but less well by third grade, when school tasks demanded more than factual recall. In contrast, the literacy background of the townspeople's children largely matched that of school and led to school success. In the second part of *WWW*, Heath and

the teachers developed strategies for connecting home and school language and literacies. Similarly, Heath and Mangiola (1991), rejecting the label “at risk,” referred to “children of promise” and described effective classroom literacy programs and strategies for culturally and linguistically diverse students.

While Heath did not detail the language and literacy practices of mainstream middle-class “townspeople” in *WWW*, she did so with former student Shelby Wolf in their joint analysis of Wolf’s daughters’ interactions with their parents around books, which they referred to as “the braid of literature” (Wolf & Heath, 1992). Their work documented literary language and imaginative play in the girls’ preschool and early elementary years literacy development and socialization. The analysis of literary events emphasized the use of a sociocultural lens to magnify relations between oral and written language and cognitive styles. Heath also collaborated with Wolf in England, exploring the role of language as students created visual and dramatic arts.

Though much of Heath’s research centers on learning environments beyond the school, her micro analyses of how young people interact in youth organizations, community sports, and after-school collaborative projects illustrates the vital importance of subject-matter knowledge transmitted within schools. She also illustrates the cultural lag of academic language in comparison with everyday language uses. She provides comparative analysis of peer interactional language practices and the communication demands of financial literacies and the world of employment.

Consistent with her focus on youth in out-of-school settings, much of Heath’s ethnographic fieldwork from 1987 to the present has been with young people in poor and working-class community organizations in the United States, England, Sweden, and the townships of Johannesburg, South Africa. She has illuminated social and language development of youth heavily immersed in the arts and sciences, including environmental projects, social justice, enterprise development, and educational inclusion. By working with peer and adult mentors on sustained projects that are deeply meaningful, youth develop the language and literacy skills necessary to contribute to the wider learning communities around them (Heath, 1993). Far more often than in the 1970s when Heath researched *WWW*, she found that the language development of older children and adolescents takes place largely in the space of communal activities and “roles that legitimate membership and overarching purpose of the group” (Heath, 1999, p. 72). These settings account for the positive correlation Heath found between increasingly complex language of adolescents and their sustained involvement in purposeful planning and work in community organizations. Within these groups, young people learn through observation, experimentation, and intense communal participation. When young people take on these responsible roles, they experience the importance of organizational, scientific, and mathematical knowledge. Additionally, Heath has found that young learners both interpret and employ the use of multimodal literacies as they gain competence in linguistic arenas focused on problem solving and group goals (Heath & Wollach, 2007). She calls for linguists to resist the seductiveness of studying only the utterances of young children and to give more attention to the language development of older youth (Heath, 1998, 2008).

Heath’s *Words at Work and Play: Three Decades in Family and Community Life* (2011b) follows families of Roadville and Trackton across three generations, from the recession of the early 1980s (chronicled in Heath, 1990) through the recession of 2008. She weaves micro-patterns of home and community life into a tapestry of macroeconomic changes after the textile mills closed and families relocated in search of employment. Everyday patterns of language use among peers have shifted syntax, genres, and styles in relation to patterns of play, work, and solitary technology use. Talk tends to center on the present with strong emphasis on the performative. Deliberations around project development, imagined scenarios, and problem solving occur primarily in collaborative projects either in families

or in after-school and weekend peer activities. Exploratory play outdoors and in creative building and art-making projects has moved indoors where entertainment, communication, information searches, and work take place through electronic technologies. Heath (2010, 2011a) heralds new language and literacy opportunities around joint community-based projects, such as community gardening, environmental action, the arts, and local social issues.

One of Heath's contributions is reflection on her own work. Heath (1993) noted that deCastell and Walker (1991) revealed how her literary experiences influenced *WWW*, employing the romance (and disenchantment) of the child, cycles of fate, and power struggles. Growing up as one of a few White children in a predominantly Black community in the southern United States, Heath described her childhood as bicultural and African American Vernacular English as one of her dialects (1993, 2011a). Her early bicultural socialization gave her a unique perspective for studying the communities of Roadville and Trackton, although she faulted herself for rarely including her own speech in reported conversations in *WWW*. In *Words at Work and Play* (2011b), she admits herself into the text as speaker and coparticipant in the families' lives narrated in the volume.

In addition to challenging herself as an ethnographer, Heath also challenges educational researchers. In a review of key contributions of linguistics to the study of language in education, Heath (2000) highlighted ways in which microstructural linguistic elements relate to macrostructures, such as classroom routines or school policies; she called for future educational researchers to ground themselves in linguistics and other disciplines, such as anthropology, sociology, or psychology, that are related to understanding the context of language use. Her research methodology text *On Ethnography* (Heath, Street, & Mills, 2008) provides detailed advice on collecting data through extended observation, artifacts, conversations, interviews, textual sources, and immersion in the field. Heath et al. emphasized asking open-ended questions, disrupting dichotomies, conducting thorough literature reviews, using the constant-comparative framing of data collection, generating conceptual memos, and building theory.

Heath's detailed accounts of language and literacy in communities across the globe have enlightened and challenged linguists, ethnographers, anthropologists, and educators. Future contributions are likely to illuminate the worlds of young people in "artsience," including the exploration, creation, design, and promotion of youth projects in music and video production, outdoor adventure, environmental conservation, and ecotourism ventures.

Hedges

WILTRUD MIHATSCH

History of the Term

Inspired by the idea of degrees of category membership as developed by fuzzy set theory, Lakoff (1972, p. 195) coined the term “hedge” for “words whose job is to make things fuzzier or less fuzzy.” His definition of hedges thus includes both expressions such as *sort of* or *roughly* as well as *strictly speaking* or *par excellence*. Although Lakoff focuses on the semantico-logical properties of hedges, he also mentions the importance of discourse aspects and hedged performatives like *I suppose that*, which Robin Lakoff had pointed out to him (Lakoff, 1972, p. 213). The term “hedge” itself is inspired by the expression “to hedge a bet” and alludes to the discourse function of reducing communicative risks. The term is adopted very quickly, however, the focus soon shifts to pragmatic aspects of hedges, and mitigation, that is, the reduction of the force of speech acts. This shift can be seen in Fraser (1975), who further develops the analysis of hedged performatives. Fraser (1980) then extends his analysis to mitigation in general, that is to linguistic procedures reducing negative effects on the speaker or hearer. Brown and Levinson (1987) analyze the use of hedges serving negative politeness, that is minimizing the infringement upon the speakers’ or hearers’ autonomy. Most pragmatic analyses are based on data from spoken informal language, but an increasing number have looked at academic and professional communication, for instance Prince, Bosk, and Frader (1982). The term “hedge” is expanded to include the mitigation of speech acts, and also restricted to hedges making semantic categories fuzzier, therefore excluding “less fuzzy” hedges such as *strictly speaking*, as in Prince, Bosk, and Frader (1982). They employ the term “hedge” to refer both to more fuzzy hedges as discussed by Lakoff (1972) affecting category membership as in (1), which they call “approximators,” as well as those operating on the illocutionary level, which do not affect the semantic content of an utterance and which they call “shields,” as in (2):

1. His feet were **sort of** blue.
2. **I think** his feet were blue. (Prince, Bosk, & Frader, 1982, p. 85)

In a similar vein Hübler (1983) classifies hedging expressions according to the linguistic level they operate on, and distinguishes understatements on the propositional level from hedges in a narrower sense, which reduce speaker commitment. A comparable distinction based on the nature of the linguistic element modified by a hedging expression can be found in other studies. Caffi (2007) suggests the most complex and detailed classification to date. Her “bushes” correspond to “approximators” in Prince, Bosk, and Frader (1982), while her use of the term “hedge” refers to mitigation on the speech act level. She reserves the term “shield” for any kind of deictic shift leading to mitigation.

All these analyses start with mitigating functions and then set out to explore linguistic expressions fulfilling those functions. Another strand of research concentrates on particular hedging expressions such as *sort of* and *kind of* and their functions (see, for instance, Aijmer, 1984 and Kay, 1984). In recent years this approach has gained impetus with large corpora available for form-based searches. Aijmer (2002) investigates the discourse effects

of *sort of* as well as list extenders such as *and that sort of thing*. This approach is mainly found in studies that consider hedges as pragmatic markers, and is also adopted in diachronic analyses. The changes leading to hedging expressions are usually considered grammaticalization or pragmaticalization processes (see, for instance, Aijmer, 2002). Furthermore, hedging phenomena are often analyzed in other contexts, for instance in the context of metadiscourse and metalinguistic functions, an important aspect of many hedges. Shields, in particular, show a certain overlap with (epistemic) modality and evidentiality. The emphasis on discourse functions has also led to a series of analyses, the most important being Channell (1994), which study approximation as a subtype of purposive vagueness, beside placeholders and indefinite quantifiers, which all avoid precision. Thus we observe a shift from semantic analyses of hedges to studies of hedges in use. This tendency explains why studies of hedges in terms of illocutionary force, that is shields, now prevail and why in many studies the distinction between approximators and shields is not taken into account. However, this may also be due to the difficulty of pinpointing the exact effect of a hedge in context. Despite this serious problem and although many hedges such as *like*, *sort of*, *kind of* are now polysemous, the difference between approximators and shields (following Prince, Bosk, & Frader, 1982) is linguistically fundamental. The distinction can be seen in diachrony, since in most cases one function is more basic, and the other derived. Synchronically, one of the two functions may arise as an implicature, which may in some cases become part of the conventional meaning of the expression (Mihatsch, 2010).

I will therefore give an overview of the different functional types of hedges following Prince, Bosk, and Frader (1982). Formally, hedges can be adverbs, adjectives, modal verbs, list extenders, suffixes, parentheticals, or, when they are well entrenched, pragmatic markers, but also non- and paraverbal devices such as gestures and intonation. Furthermore, approximation is not necessarily flagged by hedges. Relevance theory and the new field of lexical pragmatics (Wilson & Carston, 2007) study contextual effects such as narrowing and loosening, that is metaphorical extension and approximation, as an outcome of hearers' interpretations of lexical expressions guided by the principle of relevance at utterance level.

More detailed overviews of the state of the art can be found in Caffi (2007), Clemen (1997), and Kaltenböck, Mihatsch, and Schneider (2010); see also Schröder and Zimmer (1997).

A Classification of Hedges

As mentioned above, Prince, Bosk, and Frader (1982) offer a useful, not too fine-grained, function-based systematics of hedges, which distinguishes between approximators and shields. Approximators create a semantic effect. They enlarge the extension of another linguistic expression and correspond to Lakoff's (1972) "more fuzzy" hedges. Within the category of approximators, Prince, Bosk, and Frader (1982) distinguish between adaptors such as *sort of*, which render lexical categories more flexible, and rounders such as *roughly*, which signal imprecision in the numerical and temporal domain. Shields are further subdivided into plausibility shields such as *I think*, expressing doubts, and attribution shields such as *presumably*, which weaken speech acts by attributing information to a source other than the speaker. Although these distinctions are linguistically fundamental, a closer look at the polysemy patterns of hedges, as well as their discourse effects, clearly reveals rather fuzzy categories with many transition zones.

Approximators

Prince, Bosk, and Frader (1982) further distinguish between adaptors and rounders within the class of approximators. From a semantic perspective, adaptors are used to broaden

the lexical meaning of nouns, adjectives, and verbs in order to accommodate referents or concepts not usually referred to by the unmodified expression, but sharing some, though not all, of the defining features of the lexical expression modified by an adaptor. The relation between the literal, narrower meaning of the modified expression and the target concept is that of similarity. Unsurprisingly, many of the most frequent adaptors are derived from expressions establishing similarity relations, as with the comparison marker *like*, and also—via an intermediate step—*kind of* and *sort of*. Certain adaptors have a deintensifying effect when used with gradable lexemes, as in *sort of tall*, or express near-accomplishment when used with telic expressions, as in *practically finished*. These scalar effects can be more or less strong. Quirk, Greenbaum, Leech, and Svartvik (1985, pp. 597–602) distinguish several types of “downtoners” according to the strength of their deintensifying effect.

As for their discourse functions, adaptors without scalar effects are used for the description of ad hoc concepts, and they may help to compensate for memory loss, lexical gaps, and word-finding problems; thus they are associated with typical problems of speech planning. Depending on the participants and the topic of conversation adaptors may adapt the degree of precision. Derived from uses of adaptors flagging metaphors, which are a special case of similarity-based transfer, some of the more entrenched adaptors may indicate marked uses such as special idioms, figurative uses, connotations, style shifts, and so on (Aijmer, 2002, chap. 5). These uses are clearly metadiscursive and create a certain distance between a speaker and an utterance. This also explains why they may become rounders, as in the case of *like* (Mihatsch, 2010).

Another derived function is the use of both scalar and non-scalar adaptors as mitigating devices. Directive speech acts such as face-threatening orders, and assertions expressing strong opinions, tend to be softened when they contain approximators. Mitigation, which softens speech acts, can then arise as a result of implicatures, as pointed out by Fraser (1980, p. 344). Certain adaptors, such as *like*, have become fully entrenched as shields.

The highly productive implicatures and the frequent semantic changes which may fossilize those implicatures explain why the boundaries of the categories as defined by Prince, Bosk, and Frader (1982) tend to be fuzzy, and why forms such as *sort of*, *kind of*, and *like* are now polysemous and are used as adaptors, downtoners, rounders and shields.

Semantically, rounders such as *approximately*, *roughly*, *about* enlarge the extension of numerals and/or temporal expressions and thus have the same effect as adaptors. However, rounders are expressed by another set of linguistic items, although there are some overlaps, mainly as a consequence of functional changes (see Mihatsch, 2010). The semantic effect of rounders can be described as opening up a zone around a value on a scale, but not as a relation of similarity with a prototype as in the case of adaptors. Since time indications and numerals are conceptualized by the aid of scales, many rounders are the result of spatial metaphors, as in the case of *about* and *around*. Like deintensifying adaptors, some rounders may be limited by boundaries: a maximum in the case of *up to*, a minimum in the case of *over*.

Rounders are used when more precise information is not available or not required. They may help to reduce the risks a speaker runs when referring to quantities or temporal information. Like adaptors they may thus soften assertions or orders on the utterance level. However, at least in English, this function is still not fully conventionalized in particular rounders, but may arise as an implicature. Unlike adaptors, rounders are not used to compensate for word-finding problems since numerals and temporal indications are highly frequent linguistic items, and since rounders cannot signal metaphors they do not flag stylistic markedness. All in all, rounders seem to fulfill a much more limited array of discourse functions, and are therefore less pragmaticalized than adaptors.

Shields

Shields do not modify the semantic content of an utterance, but weaken the force of speech acts, that is, they operate on a pragmatic level, and therefore have wider scope than approximators. Prince, Bosk, and Frader (1982) further subdivide this category into plausibility shields and attribution shields, according to the underlying communicative strategy leading to mitigation. Similarly Caffi (2007, pp. 266–9) distinguishes several subtypes of mitigation devices on the grounds of the strategies involved. She chooses the term “hedge” for expressions softening speech acts, for instance by weakening the authority of the speaker (*if I am right*), by expressing doubts concerning the correctness of execution of a speech act as in *so to speak*, *how shall I put it?*, or the reduction of speakers’ or hearers’ obligations of belief by epistemic means and subjectivizing devices such as *perhaps*, *in my opinion*. Many modal particles also belong to the category of hedges, although the link between modal particles and hedging is not usually made in the literature, as Clemen (1997, p. 243) points out.

Within the group of hedges Caffi furthermore distinguishes different types on the basis of the modified speech act type, thus on the function rather than the strategy involved, and opposes “lenitive mitigation,” mitigation affecting directive speech acts which reduce hearer obligations, and “tempering mitigation,” modifying assertions by weakening speakers’ commitment (Caffi, 2007, pp. 85, 220–4). Shields are therefore important devices operating on an interpersonal level, which help to soften potentially face-threatening acts, but may also establish a relation of solidarity between speaker and hearer or reflect differences regarding social status. These functions also explain distinctive gender-based usage patterns.

Some shields such as *like* are not specialized in any way, but seem to be all-purpose shields. Caffi’s category of shields, that is mitigators based on any kind of deictic shift, includes some attribution shields of Prince, Bosk, and Frader (1982), and includes strategies such as passive voice, backgrounding, and so on.

At utterance level, according to Prince, Bosk, and Frader (1982), shields—as well as Caffi’s hedges—may be interpreted as approximators when taking a narrow scope, just as approximators may be used for mitigation.

Applications

In line with the tendency to study pragmatic rather than semantic aspects of hedging, this phenomenon has become an important topic in a variety of applications.

Most applications rely on methods of discourse and conversation analysis. Frequently studied discourse types in the domain of hedging research are political discourse, institutional communication, medical discourse, academic discourse, media discourse, and communication in educational settings. It is interesting to note that many hedges are associated with certain registers; compare, for instance, a colloquial rounder such as *about* with a more formal rounder such as *approximately*. However, these restrictions may disappear when colloquial elements enter into institutional discourse and vice versa; see Fairclough’s notion of “conversationalization of discourse” (Fairclough, 1992).

Text and discourse analyses also consider questions traditionally treated in rhetorics, since hedging can be a very efficient technique of persuasion. A related line of research investigates the effects of hedges on readers or listeners. Recall and acceptance of text content tends to be enhanced by the use of hedges (Crismore & Vande Kopple, 1997).

Another field of application deals with sociolinguistic aspects of hedging, that is the influence of parameters like age, gender, social status, power, ethnicity, and educational background on the use of hedging devices. Crosslinguistic analyses of the use of hedging reveal interesting differences between languages and cultures. For instance, Crismore,

Markkanen, and Steffensen (1993) find that Finns use more hedges than Americans, and Finnish men more than women.

A new line of research exploits patterns of hedging for diagnostic purposes. Elisabeth Gülich and Martin Schöndienst employ methods from conversation analysis in order to distinguish between epileptic and nonepileptic anxiety (see Epiling, <http://www.uni-bielefeld.de/lili/forschung/projekte/archiv/epiling>).

Studies dedicated to second language acquisition and second language teaching point to the importance of mastering the use of hedges, especially when learning a new language.

Conclusion

The history of hedging research is remarkable since the study of this ubiquitous phenomenon in both spoken and written language has gained more attention now in several fields of applied linguistics and pragmatics than in classic areas of linguistics such as syntax and semantics. However, there are still many areas in applied linguistics where hedging research needs to be undertaken, especially in languages other than English.

Heller, Monica

MELISSA MOYER AND MIREILLE MCLAUGHLIN

Monica Heller was born in Montreal, Canada and was trained in Linguistics and Anthropology at University of California, Berkeley where she received her PhD. Her career has been dedicated to understanding the role of language in social, economic, and political processes. She has followed the changing linguistic ideologies underlying the transformations of Francophone Canada. She takes a critical interpretative approach to the study of language and society. For Heller, a critical sociolinguistic perspective is concerned with problematizing relations of power together with a focus on language understood as *practice* and as a form of *social action*. Key to this position is the idea that all social reality is constructed. In practice this approach consists in looking at situated language use in interactions in order to see how language is mobilized in processes of categorization. Heller observes that linguistic practices and ideologies are mobilized to legitimate processes of social exclusion that take place in key institutions of society linked to the nation-state and work sites of the new economy. Another element of this approach is a critical self-reflection with respect to the location of her research and the production of academic knowledge in the deployment of power relations. Heller's understanding of ongoing social processes of structuration that are shaped—but not determined—by neoliberal economic practices is at the root of her approach to language and power. Communicative creativity or the agency of social actors is constrained by the unequal distribution of communicative resources, a fact that results in positioning people in different ways in terms of their access to the resources or services provided by key social institutions. Institutional and individual trajectories intersect, creating discursive spaces where power over valued or legitimate communication is controlled, hence having important consequences for access to key material and symbolic resources.

Ethnographic fieldwork and the study of multiple sites is one of the principal means used for showing the interconnectedness of wider social processes with institutional ideologies, interpersonal relations, as well as social categories of language and identity. Ethnographic data consisting of participant observations, field notes, interviews, discourses, interactions, images, and institutional documentation are brought in to triangulate her analyses and to make the connection between interactional orders and institutional processes. Heller has applied this methodological perspective, together with these conceptions of language and society, to her work on bilingualism and code switching as a resource, schools as institutions of social (re)production, postnationalism and language practices in a global world, and the commodification of language in key sites of the new economy.

Bilingualism and Code Switching

Heller's work on bilingualism and code switching contests the notion of bilingualism as the coexistence of two objective, bounded linguistic systems. It also argues that language is not simply connected or correlated to societal and cultural factors but, rather, it is a practice that is socially and politically embedded. Linguistic ideologies linked to discourses of the nation-state that developed in the 19th century in particular have favored notions of monolingualism as the ideal norm for conceptualizing languages; as a consequence,

bilingualism constitutes, in nationalist ideologies, a threat to the linguistic and cultural unity desired. The communicative forms and practices associated with bilingualism and multilingualism show, first, how language is connected to social process and, second, how social meanings and relations of power are established and maintained. Heller took up in her early work the notion of code switching as a particular kind of language practice. She looked at a Toronto-French language minority school and a Montreal brewery where code switching was understood as another resource available in the speech economy of the community. Code switching, she found, was a way to manage conflict between French and English speakers at a time when the Canadian and Quebec governments were undertaking the *francisation* of the public and private political and economic spheres. It is also understood as a shared frame of reference that allows for interpretations of solidarity (convergence) or distancing (divergence). In cases where shared knowledge is not available, code switching allows interlocutors to be purposely ambiguous. This attention to code switching at the micro interactional level in schools and the brewery corresponds to Heller's concern about the way the political and economic changes in Canada were experienced by individual members of the community. When framed in a larger social context of *francisation* and a shift toward an economy of services, code switching can be used as a strategy by drawing upon symbolic resources in order to gain access or to deny access to valued resources in a given marketplace. Inspired by the thinking of Bourdieu and Gumperz, Heller also holds that valued linguistic resources in a bilingual community are unequally distributed where certain people decide what ways of speaking count as legitimate language in a given context.

Minority Schools

Heller's interest in school resides in the school's role as a state agency of social and cultural reproduction but also as a site of struggle and contestation of centralized state policies in the management of minority language education. School, according to Heller, legitimizes the distribution of particular types of linguistic and cultural capital that have an accepted value in Francophone Canadian and global labor markets. It also is a site of struggle around the definition of legitimate national identities, in addition to a space of struggle for the social reproduction or transformation of a specific linguistic order. It becomes a space where state institutions manage the multilingualism of its citizens.

The French-language minority schools she studies in Toronto, Canada arise from the mobilization of nationalist ideologies that seek to construct schools as homogeneous discursive spaces with a standardized language that serves to define minority identity, thus reproducing ideologies of language as a bounded and territorialized system. School becomes an institution confronted by the diversity brought by multilingual speakers from other parts of Canada and the French-speaking world which challenge traditional ideas associated with Francophone nationalism. Heller analyzes how the nationalist understanding of Francophone identity creates spaces of inclusion and exclusion and leads to struggles between the school administration, staff, parents, and students around the notion of legitimate Francophone cultural and linguistic capital. The link between language and identity connected to the Canadian state and its educational program is also explored by examining language, as ideology and as practice and the way it is key in producing and contesting social inequalities within the terrain of the school.

The work in schools focuses on linguistic resources (such as the knowledge of standard French, vernacular French or English, among other languages) and the way they circulate. This leads Heller to examine the manner in which these resources have different values for social actors in the discursive space of the school and to look at how this is linked to

the labor market, where she studies the stakes of the emerging new economy. Interviews with parents of school students indicated that social actors participating in minority spaces such as the school were increasingly abandoning the politics of Francophone identity in favor of a new, more pragmatic position where access to multiple linguistic and cultural resources was considered a valuable asset in gaining access to and being successful in activities of the new economy. The school context leads her to an understanding of some of the ways the commodification of language begins to be taken up by French minority speakers.

Postnationalism, Language, and Social Process

Heller's understanding of postnationalism is related to the role of language in how the nation-state is coping with social, political, and economic changes since World War II. The traditional welfare state has been key in the development of Francophone institutions and its discursive spaces in Canada. Today, the Canadian nation-state is currently being challenged and forced to reexamine its role in a globalized world where there is a much greater diversity in all spheres of life, brought about by a greater mobility of people, information, and goods. One of the changes that the postnationalist state is facing in its redefinition is a shift in discourse, which has moved from the protector role of the state as the guarantor of the rights and welfare of its citizens to a neoliberal discourse of the state as a mediator for economic development and profit. Some of the social processes Heller looks at where the changing role of language can be observed are the growth of the service economy, the adaptation of Taylorist management techniques of control and regimentation to activities of the new economy, and the flexibility in work sites that involves the mobility of production sites as well as workers who need the ability to communicate in certain ways and in more than one language or variety. The sites Heller has studied over time where these processes can be observed include call centers, beer brewing factories, developments in the mining of profitable raw materials, ethnolinguistic cultural groups involved in the organization of festivals at tourist sites, schools, and niche markets where local branding and authenticity get constructed. A close-up look at the mobilization of language and discourses in the multiple sites studied by Heller across time and space show how linguistic and material resources are produced and distributed and how the political-economic conditions position and constrain social actors and their chances of mobilizing these resources in given contexts.

Commodification of Language

The commodification of language, according to Heller and others, has become a theme of current sociolinguistic interest because of the ways the new globalized economy is taking up language. As the exchange of information has become central for establishing and maintaining social and commercial ties, language and multilingualism skills play a key role in the emergence of global networks. The expansion of markets beyond the boundaries of nation-states requires the ability to communicate in other languages in order to buy and sell products and services. Information and communication technologies are another important dimension upon which the current economy hinges, and these new forms of communication provide a practical means for overcoming time and space and the constraints they traditionally imposed on communication used for the expanding global markets. An economy that is becoming increasingly service-based also depends on language and communication.

The political-economic conditions Heller observes in the case of Canada show the shift from discourses about language that take up the protection of identity to discourses about its commodification or its value on an economic market. This change is challenging the state- and community-based systems of the production and distribution of linguistic resources. The emphasis on the exchange value of language enters into tension with older ethnonationalist ways of defining both authentic and standard language performances on the basis of community. Heller notes, however, that while nationalism is challenged by the new economy, it is often mobilized to market niche products in a global market.

Her research shows how linguistic practices are used by producers to add value to many different kinds of local product—for example, the way French-speaking regions sell themselves as “perfectly” bilingual to potential call-center investors, or how Quebec producers of cheese and soap use heritage to tap into images of an authentic French tradition, or how tourist sites make symbolic use of linguistic varieties to attract a global public. As commodification opens up new markets, new actors are competing with established elites in order to position themselves and their products in the new economy. Language becomes a terrain of social action as actors compete to define what counts as legitimate, authentic, and standard linguistic performances. The commodification of language thereby raises tensions with regard to questions of authenticity and standardization. This ability to produce, access, or measure either an authentic or standard language performance is a source of power in the new economy.

Heritage and Community Languages

TERRENCE G. WILEY

The expressions *heritage* and *community* languages generally refer to minority languages used in countries where there are dominant or official languages that have greater status and/or numerical dominance. In the USA, for example, the expressions “heritage language” and “heritage language speaker/learner” have been in vogue since the late 1990s. Although the labels seem new, some heritage and minority community languages predate the founding of the country (Fishman, 2001). The various labels that can be applied to minority languages are often problematic because a single label applied to languages with complex historical and sociocultural situations is insufficient to capture all aspects of their conceptualization. Moreover, the labels applied by linguists do not always correspond to those of the speakers themselves. Thus, defining heritage and community languages can be problematic.

There is no consensus regarding the use of these terms. In the USA, for example, the label “heritage language” is sometimes used to refer to immigrant, indigenous, and former colonial languages. In Australia the expression “community language” is used to refer to immigrant languages. Before “heritage language” gained popularity in the USA, it previously had been used to refer to minority immigrant languages in Canada. Some of the reservations about the expression are that it conveys a sense of minority status, which is backward looking, focused on past traditions, rather than a sense of vibrancy that reflects either contemporary life or future possibilities (Baker & Jones, 1998). Thus, for some, “community language” may be preferred. Despite these issues, the heritage language label has shown considerable resiliency, especially in the USA. For the purposes of this discussion, both expressions will be taken as equivalent.

When the label is applied to those learning their professed heritage language, the expression raises some questions regarding the relationship between language proficiency and family or ancestral identity. The issue becomes, “Who can legitimately be a considered heritage language learner? Which is more important, affiliation with an ethnolinguistic group or proficiency in the target language?” (Wiley & Valdés, 2000, p. iii). From an identity perspective, one can be considered a heritage language learner even though she or he may have little or no proficiency in the heritage language. Proficiency, however, is important from the viewpoint of educational placement. Addressing and sorting out the needs of heritage learners, who have some knowledge of—and proficiency in—their heritage language, versus those who are truly second or foreign-language learners has proved to be an important placement and instructional consideration for many language programs. Thus, the programmatic labels we apply to heritage language learners are important, because they help to influence the perception and standing of the learners and their languages. Deciding what types of learners should be included under the heritage language label likewise raises important issues related to group inclusion and exclusion and individual identity. In language revitalization efforts, ethnolinguistic affiliation is important because some learners, who have a desire to establish a connection with a family or ancestral language, may not be speakers of that language yet may feel a strong obligation to learn it. Nevertheless, for instructional purposes, assessment of proficiency is also important. Thus, for pedagogical purposes, Valdés (2000) has defined a heritage language speaker as

one “raised in a home where a non-English language is spoken . . . who speaks or merely understands the heritage language, and who is to some degree bilingual in English and the heritage language” (p. 1).

Additional questions can be asked about which “heritage” language best represents immigrants who were second language learners of the dominant language in their home countries because they were speakers of minority languages or dialects in their countries of origin. Consider the rapid growth of Mandarin as the heritage language of choice among Chinese immigrants. Many from China speak mutually unintelligible Chinese “dialects” as their home languages. After immigrating to their new country, they may encourage their children to study Mandarin—not because it is their native language or regional dialect, but because it is the larger common language of China. The same types of choice may be made among immigrants from South Asia, who may encourage their children to study Hindi if they are from India or Urdu if they are from Pakistan, rather than their local or regional South Asian language. The choice between Hindi and Urdu, which are mutually intelligible but use different written scripts, may be further influenced by religious affiliation, with Muslims opting for Urdu and Hindus choosing Hindi. African Americans, on the other hand, may want to study Swahili because it is used as a lingua franca in parts of Africa, even if it is not their ancestral mother tongue. In these cases, the choice of a “heritage” language may actually be a surrogate that allows them to connect with a wider ancestral culture through language. These are choices that cannot be made by language planners, but must be made by the members of the ethnolinguistic groups themselves (Wiley, 2001a).

Program and Sociolinguistic Considerations

In describing educational programs for heritage language learners, various labels other than “heritage” are being used, such as “foreign” or “bilingual” language education. Although heritage language learners often enroll in these programs, the programs themselves may not be overtly attuned to the students who populate them. The vast majority of those being taught Spanish in the USA, for example, are taught Spanish as a foreign language. There are, however, a minority of programs that are designed as “Spanish for Native Speakers” (SNS) (Wiley, 2007). These programs recognize that those enrolled have considerable knowledge and functional proficiency in Spanish but have not had the opportunity to develop literacy or a wider range of social registers in the language.

As previously noted, “community language” and, we may add, “community-based” language education are terms that may be used as alternatives to the heritage language education label. This emphasis on community is important because of the vital role that communities play in promoting the intergenerational maintenance of languages. Frequently, this role has been played outside of formal schooling or publicly funded education. Many immigrant community language programs are supplemental. They are conducted through churches, temples, mosques, or secular volunteer efforts. Similarly, there are many indigenous language community-based efforts to help preserve and promote native languages. To ensure that heritage language programs are relevant to the community, it is essential that members of the community be directly engaged through their own agency in promoting their languages in ways that are authentic for their members and reflective of their aspirations and interests (Corson, 1999).

Determining what the educational emphasis of a program should be is important for ensuring that the language learning experience will be meaningful for the members of the community. Language and instructional choices involve sociolinguistic considerations regarding which forms and varieties of language will be taught and how much emphasis

should be placed on literacy or oral proficiency (Horvath & Vaughan, 1991). Informal or colloquial varieties of languages may vary considerably from their written standard forms. Language learners may have knowledge of, and some proficiency in, the informal varieties but may not have mastered the formal standard used in school or in social situations requiring more formal registers. Regional varieties of a language may be used colloquially by members of a community along with a standard variety. A written standard taught in school can vary substantially from the variety used at home. Within the community, attitudes toward different dialects also may diverge from those of teachers, who focus only formal varieties. Thus, the characteristics of community language varieties, as well as the attitudes toward those varieties, need to be understood by those teaching heritage and community languages (Horvath & Vaughan, 1991; Wiley, 2001a).

Diglossic functions of language are also important to consider because different varieties of a language may be used to fulfill different social functions in the community. Regional varieties of Arabic, for example, are very different from classical written Arabic and are not used in the same social contexts as contemporary spoken Arabic. Thus, heritage and community language educators also need to be aware of how different varieties function and who uses what varieties for what purposes in specific social contexts (Horvath & Vaughan, 1991).

For many heritage and community language speakers, two or more languages are used by their communities to fulfill major communicative functions. In a Chinese heritage community in the USA, for example, Taiwanese (southern Min) may be used for informal purposes, Mandarin for others, and English for still others. Thus, in some situations three or more languages may be used together, with considerable code switching among speakers. Not all the members of the wider heritage language community will be equally fluent in all of the languages used to fulfill all of the major communicative functions. Thus, it is important for language educators to gain an appreciation of the different roles that different languages play in multilingual communities and the different attitudes toward them. Again, it is also important to remember that the judgments of linguists and language educators regarding different language varieties are not always parallel to those of members of the language community to be served. Therefore, it is important to keep a community focus in designing curricula.

Policy Considerations

Historically, in the USA and other countries with large immigrant populations, heritage language maintenance and promotion issues have often been framed from an immigrant perspective, with only secondary focus on the presence of indigenous language minority communities. From an immigrant language perspective, the English-speaking majority tends to see the loss of heritage languages as a kind of rite of passage into the dominant language and culture. Therefore, efforts to encourage the preservation and promotion of immigrant heritage languages pose challenges if there is little governmental support, a situation which results in preservation efforts being largely left to the resources and efforts of language minority communities themselves. These efforts tend to be short lived. In the USA, for at least the last century, there has been a three-generational shift to English, and there is recent evidence that for some groups this is becoming a one-generational shift (Veltman, 1983; Rumbaut, 2009).

The role of governments in the formation of heritage language policies is another important area for consideration. In countries with centralized language policies, the government may determine the status and legitimacy of minority languages. Under federal systems, such as in the USA, language policies may be determined at the federal, state, or local

level. States may establish their own policies as long as they do not conflict with federal law. Localities may do the same as long as they do not contradict federal or state policy. US federal laws that permitted bilingual education as an accommodation to help minority children transition to English, for example, became an area of considerable misunderstanding and contestation.

Some opponents of federal- and state-funded bilingual education contended that its real goal was to promote minority languages. They argued that it is improper for the government to promote any single language other than English. Some proponents of bilingual education, however, have noted that transitional bilingual programs further the process of Anglification because their target outcome is promoting English rather than bilingualism and biliteracy (Ruíz, 1995). With the exception of recent modest federal support for the preservation of Native American languages, and the State of Hawaii's recognition of Hawaiian as a co-official language with English, there has been little governmental endorsement of heritage languages in the USA. Historically, at the state and territorial governmental levels there is a longer record of restriction. This was particularly the case during and shortly after World War I, and again in recent decades with the reemergence of the "English-only" movement (Wiley, 1998).

Most efforts to promote heritage languages have been carried out through community-based efforts, in weekend or supplemental classes after school. In the USA, there have been several constitutional challenges contesting language restrictionism. Two noteworthy cases are *Meyer v. Nebraska* 262 US 390 (1923), which overturned a state statute making the teaching of German illegal, and, of particular importance for heritage and community language education, *Farrington v. Tokushige* 273 US 284 (1927), wherein the US Supreme Court affirmed the right for heritage language instruction through private and community-based efforts. During the late 19th and early 20th centuries, the US federal government prohibited the use of Native American languages and mandated Native American children to attend government-run, English-only Indian boarding schools. Since the early 1990s the federal government has reversed its policies and has recently appropriated modest funding for the promotion of Native American languages (Wiley, 2001b).

Language policies can be categorized based on their goal. They may seek to promote, accommodate, restrict, or suppress a language. Ruíz (1995) makes an additional distinction among three types of promotional policies: *endoglossic*, *exoglossic*, and *mixed* language policies. "Endoglossic policies are those that give primacy to and promote an indigenous language of the community" (p. 75). In the USA, indigenous languages tend to be local and regional in use, but they are not generally taught as languages of wider communication. *Exoglossic* policies are intended to promote languages of wider communication. *Mixed* policies attempt to promote languages both within and beyond the local or regional community. Policies designed to preserve native languages in the USA are, thus far, largely *exoglossic*—intended to affect local and regional indigenous communities.

What has been the impact of various language policies on the experiences of different groups of heritage and community language speakers? Although there is substantial evidence that prior to the 20th century there was a language policy climate of relative tolerance toward European immigrant languages and their speakers, the experience of enslaved African Americans and Native Americans was marked by overt efforts to eradicate their languages and cultures (Toth, 1990; Wiley, 1998). Other groups, such as speakers of Hawaiian, experienced a parallel fate (Benham & Heck, 1998).

Thus, the recent shift toward Hawaiian and Native American languages is of both symbolic and pragmatic significance in advancing a reversal of language shift and their maintenance (Wilson, 1999). McCarty and Watahomigie have also noted a number of successful American Indian programs that have been implemented with federal bilingual education funding (McCarty & Watahomigie, 1999). Given the vicissitudes in the history

of language policies toward Native Americans, Ruíz (1995), however, suggests developing endoglossic policies at least for the short term, even if in the future support for these is removed by the federal government. He reasons that “the language policy planning decisions made now will help communities achieve the continuity of tradition that has served them well up to now” (1995, p. 79). Ruíz’s recommendation is basically one of using government policies to promote heritage languages during favorable times, while relying on community-based efforts to preserve their own languages over the long term. Thus, there is a role for government-supported top-down programs as long as they are endorsed by, and congruent with, bottom-up efforts initiated by heritage and community language speakers themselves (Hornberger, 1997; Corson, 1999; May, 1999; McCarty & Watahomigie, 1999).

Heritage Language Teaching

GUADALUPE VALDÉS AND AMANDA KIBLER

The term *heritage language* has come to be used widely by those concerned about the study, maintenance, and revitalization of non-majority languages around the world. The phrase has been defined broadly as well as more narrowly. In its broadest sense, found in the sociolinguistic community, heritage language refers to any non-majority language with which individuals have a personal connection (Fishman, 2001). In this case, it is the historical and personal connection to the language and the commitment to strengthening and preserving it for future generations that is salient, regardless of the actual proficiency level of heritage speakers. The foreign-language teaching profession currently uses the term *heritage student* in a more narrow sense to refer to a student of language who is raised in a home where the non-majority language is spoken. In this case, the focus is on speakers' exposure to and level of heritage language (re)acquisition. Students may speak or merely understand the heritage language and may be to some degree bilingual in the majority and the heritage language. For language educators, the developed functional proficiencies of heritage language students are different in important ways from those of the traditional foreign-language student. This entry will discuss the concerns and efforts of the foreign-language community related to supporting appropriate instruction for heritage language students.

Within the profession of foreign-language education the use of the term *heritage language speaker* is relatively new. Many scholars trace the term *heritage language teaching* from the Canadian context, where ongoing efforts have been made to preserve and revitalize non-majority languages such as French and Ukrainian, among others. Such teaching has been known by other names as well, such as ancestral, minority, ethnic, and, particularly in Australia, community language instruction. Heritage language first became a term of general use in North America in the Standards for Foreign Language Learning (www.actfl.org/i4a/pages/index.cfm?pageid=3392), developed by the National Standards in Foreign Language Education Project in 1996. As currently used, the term heritage language refers to all non-majority languages, including those spoken by indigenous populations.

Despite having a common label, heritage language students are an extremely heterogeneous group. To deal with this complexity, researchers have proposed the notion of a continuum to describe heritage speakers' use of their first, and in some cases, second languages. For example, Polinsky and Kagan (2007) suggest a continuum model, similar to that used with Creole languages, to measure speakers' relative linguistic proximity to the language to which they were exposed as children. The field of foreign-language education continues to search for ways to describe learners more precisely who enter the classroom with strongly developed proficiencies in their ancestral languages.

In its twenty-five-century history, the foreign-language teaching profession has primarily ascribed to cognitivist (in-the-head), rather than social interactional (in-the-world) views of language acquisition and use. As a result, teachers of heritage language students often know little about language variation, societal bilingualism, or language contact. Without an understanding of the sociolinguistic factors influencing heritage language speakers, foreign-language professionals may view students' language from an overly prescriptivist perspective, focusing on the ways heritage speakers "say/write it wrong," and use a monolingual native-speaker norm to evaluate the competence of heritage language speakers.

2 HERITAGE LANGUAGE TEACHING

Such a monolingual perspective is misplaced because, as Grosjean (1985), among others, explains, bilinguals are not simply two monolinguals in one: they have acquired two knowledge systems to carry out their particular communicative needs, which may be quite unlike those of monolingual native speakers who use a single language in all communicative interactions. In this sense, heritage speakers are users, rather than simply learners, of their first (L1) and second (L2) languages. Building upon Cook's (2002) notion of the "L2 user," Valdés has suggested elsewhere that heritage language students may be more appropriately described as "L1/L2 users" (Valdés, 2005).

Most early heritage language teaching focused on Spanish-language contexts. Until the mid 1970s, foreign-language teaching professionals taught Spanish almost exclusively to monolingual Anglophones. However, the increasing number of Spanish speakers entering the country from the 1970s onward began to have a significant effect on the Spanish-teaching profession at both the secondary and the postsecondary levels. In some cases, these students were more fluent in the language than their teachers were, but they could not talk *about* the language using the terminology found in the teaching of traditional grammar. Many of these students had no experience reading and writing in Spanish, and they often spoke stigmatized varieties of their heritage language. There was little agreement among Spanish-teaching professionals about effective pedagogy for these students, but students were often seen as needing remediation that would help undo the "damage" that had been done at home.

Since that time, however, many more languages have been taught in heritage settings, and heritage language instruction has received greater research attention. The greatest challenge currently facing the foreign-language profession in teaching L1/L2 users who elect to maintain or develop their L1 in formal instructional settings is designing instruction that is not only appropriate for students' current and future needs but also based on coherent theories of instructed language acquisition for these particular groups of learners. Of the recent efforts focused on describing the features of heritage students' language, some of the most engaging work in this area investigates issues of incomplete language acquisition and language attrition (e.g., Polinsky, 2005). While this linguistic work is in an early stage, it has significant potential to influence the assessment, placement, and teaching of heritage languages in classroom contexts. What is still unknown, however, is how heritage language students' language and knowledge systems may be restructured or reshaped by formal instruction.

Pedagogically focused research into heritage language teaching has explored curriculum design and instructional methods (e.g., Douglas, 2005; Colombi, 2009), assessment (e.g., Fairclough, 2006), textbooks and materials selection (e.g., Leeman & Martinez, 2007), or a combination of these (e.g., Kondo-Brown & Brown, 2008). Some articles focused on heritage language teaching are written by practicing heritage language teachers and describe personal instructional experiences rather than empirical investigations. Other instructionally focused studies attempt to delineate differences between the classroom-based linguistic performance of heritage speakers and traditional foreign-language students (e.g., Kondo-Brown, 2005). An additional visible concern in the literature on heritage language pedagogy at the university level is the need to prepare these students to be successful in traditional university foreign-language programs, as language majors and eventually as scholars.

Related research focuses on the students and teachers participating in heritage language classrooms. Descriptions of heritage teacher-training experiences (e.g., Anderson, 2008) as well as studies of heritage teacher beliefs and practices (e.g., Lacorte & Canabal, 2005) provide insight into instructors' perspectives in the classroom. In relation to students who are placed in heritage language classrooms, the negotiation of multilingual identities is an issue that has received significant attention: Blackledge and Creese (2008), for example,

have investigated how these students negotiate identities in ways that subvert traditional “heritage” labels placed upon them.

Recent developments in heritage language teaching demonstrate the growth and expansion of this field. While Spanish, and to a lesser extent, Russian, have often been the focus of heritage language scholarship, recent publications indicate an increasing interest in the teaching of Chinese, Japanese, and Korean heritage languages (e.g., Kondo-Brown & Brown, 2008; Lee & Shin, 2008) and the teaching of Spanish in “new Latino diaspora” communities (e.g., Harklau, 2009; Bateman & Wilkinson, 2010). Linguistic research into heritage language speakers now investigates an impressive range of languages, from Armenian to Finnish to Vietnamese, and as heritage language programs become more common in these languages there will likely be an increase in pedagogically focused research about them as well. The *Heritage Languages Journal* (www.heritagelanguages.org/), an online publication established in 2003, the National Heritage Language Resource Center (www.international.ucla.edu/languages/nhlrc/), and the National Foreign Language Center (NFLC) Alliance for the Advancement of Heritage Languages (www.cal.org/heritage/) are valuable new resources available to teachers and researchers interested in heritage language teaching.

Heritage language teaching has also expanded beyond the secondary, university, and community language classrooms with which it has been traditionally associated. In the United States, for example, demand for highly skilled speakers of non-English languages has become an important focus for national defense initiatives, such as the National Security Education Program’s English for Heritage Language Speakers Program, which aims to develop and use heritage language speakers’ multilingual proficiencies. Language maintenance efforts are also undertaken in elementary schools serving immigrant children, including in-class or after-school instruction in what schools often refer to as students’ “primary” languages (e.g., Curdt-Christiansen, 2006).

Much remains to be learned about the effects of language instruction on heritage speakers, and recent publications suggest several directions for future investigations. In 2002, a panel of researchers at the Second National Conference on Heritage Languages in America outlined several key research questions relating to heritage language ecologies, ideologies, measurement, and literacy (Campbell & Christian, 2003). More recently, Polinsky and Kagan (2007) have suggested that a longitudinal study of instruction, using measurable outcomes, might provide insight into the impact of different pedagogical approaches for different types of heritage students. Heritage language teaching raises a number of important theoretical issues relevant to practitioners and researchers alike, and the field would also benefit from additional research into language acquisition processes, including language attrition and incomplete acquisition—topics that cannot be addressed fully here—as well as the acquisition and use of heritage speakers’ receptive and productive grammars, the sources of heritage speakers’ “flawed” language production, and speakers’ acquisition of multiple registers, genres, and dialects in the heritage language.

Heritage Languages and Language Policy

KENDALL A. KING AND JOHANNA ENNSER-KANANEN

Defining Heritage Languages

The term *heritage language* (HL) was first used in the Canadian context to refer to any “language other than English and French,” and intended to reference the languages spoken by indigenous (First Nation) people or by immigrants (Cummins, 1991, pp. 601–2). Clyne (1991) modified the definition for the Australian context to include any language other than English (LOTE). US researchers and policy-makers adopted this version in subsequent years.

While HL is often taken to be the language used in home or familial contexts (Campbell & Peyton, 1998), others point to HL’s broader cultural associations and significance. Fishman (1999) further broadens the definition of HL, suggesting that HL can refer to any “language of personal relevance other than English” (cited in Van Deusen-Scholl, 2003, p. 216). Kondo-Brown (2003) synthesizes Wharry’s (1993) term “ancestral” and Fishman’s (2001) three subcategories of HL: HL refers to any ancestral language, including those that are *indigenous* (e.g., Navajo or Ojibwe), *colonial* (e.g., Dutch or German in the USA), and *immigrant* (e.g., Hmong or Somali in the USA); thus the HL might or might not “be a language regularly used in the home and the community” (p. 1).

The label “heritage” has been problematized as outdated and linked with primitivism (e.g., Baker & Jones, 1998). Indeed, “heritage” suggests a trait or asset gained through birth, such as property or DNA, when language is not fixed but rather the product of interaction. Baker and Jones (1998) also note that alternatives like *ethnic* and *ancestral language* hold similar connotations while, as Van Deusen-Scholl (2003) points out, *primary* and *native language* often reflect inaccurate assessments of language competence. Outside of North America, the terms *allochthonous language*, *home language*, and *language of origin* are in wider use (Van Deusen-Scholl, 2003). In Europe, an important distinction is made between *indigenous* or *regional* minorities (RM), whose (language) rights are often legally protected, and *refugee* or *immigrant* minorities (IM), who generally do not enjoy the same status (Extra & Gorter, 2001). Despite efforts of the Council of Europe to raise the status of minority languages (MLs), many remain endangered (De Bot & Gorter, 2005). Similarly, in the USA, the position of many HLs remains fragile (Van Deusen-Scholl, 2003).

Defining HL Learners

HL learners are often differentiated into those who identify culturally with the HL versus those who speak it at home (Valdés, 2001). Similarly, Kondo-Brown (2003) points out that defining oneself as a HL learner often depends on identity orientation rather than linguistic proficiency. Van Deusen-Scholl (1998, 2003), in turn, suggests a distinction between heritage learners and learners with a heritage motivation, which aligns with Carreira’s (2004) labels “HLL1” and “HLL2.” Carreira (2004) also argues that a definition of HL learners has to take “identity, language, and family background” into consideration (p. 18).

In the USA, HL learners have been defined more narrowly as those who were raised in non-English-speaking homes, who have receptive or productive HL skills, and are to some degree bilingual (Valdés, 2001). These individuals have often received all their formal schooling in English with limited opportunities to develop HL literacy skills. In turn, Wiley (2001) suggests a more socially contextualized definition of HL learners and stresses the importance of definitions that serve to empower HL learners. These definitions are important as they “undergird decisions about course and program design, materials selection, placement and assessment of students, and teacher training” (Carreira, 2004, p. 2).

HL learners represent an extremely diverse group. In the USA, by far the largest and fastest growing HL population are Latinos, a group comprising greatly different Spanish proficiency levels, cultural backgrounds, as well as varied dialects, goals, and needs (Van Deusen-Scholl, 2003). While much of the research and policy work has focused on this population, other HLs, including Korean, Arabic, Chinese, Hindi, Persian, and Urdu, have received growing attention in recent years.

US Language Policy for Heritage Languages

US language policy (LP) for HLs has expanded rapidly in the last decade concomitant with growing recognition of a long-standing contradiction in language and education policy. Specifically, the great majority of HL speakers are schooled primarily if not entirely in English (and as a result transition to English dominance or monolingualism), and then later taught a “foreign” language (FL) in high school, college, or both, often with limited success (Wright, 2007). Most LP initiatives for HLs recognize that traditional foreign language classes are inappropriate for HL learners (Carreira, 2004) as they fail to build effectively upon the linguistic and cultural competencies that HLs have gained outside of formal schooling.

HL education policies also seek to harness the linguistic competence in HL communities as a national resource. Following 9/11, language competence was recognized as a critical and long-neglected US national security issue as it became clear that there were insufficient numbers of qualified individuals fluent in “critical languages” such as Arabic or Korean. Cultivation and training of US citizens with HL backgrounds were viewed as relatively quick and efficient means of meeting this need, and one recognized through federal funding by the US Department of Education for the National Heritage Language Resource Center (NHLRC). The Center’s mission is to develop effective pedagogical approaches to teaching HL learners, first by creating a research base and then by pursuing curriculum design, materials development, and teacher education. Additional LP work for HLs has been funded through the National Security Language Initiative (NSLI), which seeks to expand and improve the teaching and learning of strategically important world languages, in particular through the STARTALK program (<http://startalk.umd.edu/>), which aims to increase the number of Americans learning, speaking, and teaching critical need foreign languages.

In addition to these federal LP efforts, a number of schools and programs at the K-12 and university level aim to provide language instruction for HLs. The bulk of these have been directed at Spanish HL learners (Valdés, Fishman, Chávez, & Pérez, 2006). Yet substantial need remains. For example, most postsecondary institutions do not offer any HL courses (Gonzalez Pino & Pino, 2000), and while calls for teacher training for HL learners date back more than 30 years (Valdés, 1981), there are few programs or standards for training teachers to instruct Spanish to native speakers.

Looking Ahead

As suggested above, few programs are designed specifically for HL learners; most often they attend FL classes (Van Deusen-Scholl, 2003), especially at the tertiary level. More HL-specific materials, teacher training, assessment tools, and opportunities for community-based learning are urgently needed (Van Deusen-Scholl, 2003).

More generally, the field of HLs is challenged by the heavy federal emphasis on a narrow handful of “critical languages,” that is those deemed to be critical to US national defense (e.g., Arabic, Pashtu, Korean). As noted above, these HLs have benefited from substantial support, while others (e.g., Hmong, Ojibwe, Somali) largely have been overlooked (King, 2009). As widely noted (e.g., Sandrock & Wang, 2005), this narrow prioritization of a handful of select languages is short-sighted given that the languages in need will no doubt change very quickly in step with world events; a better, long-range goal would be the active cultivation of a wider and deeper pool of Americans with second language skills of all sorts.

Even more broadly, perhaps the biggest challenges to all HLs in the USA are the general immigration politics and powerful English-only ideologies that undergird a rapid shift to English. For instance, SB1070, passed in the state of Arizona in April 2010, requires that immigration status be ascertained by local law enforcement when there is “reasonable suspicion that the person is an alien who is unlawfully present in the U.S.” While what might make a person “reasonably” suspect is not legislated, one might soundly infer that speaking Spanish (or another HL) would raise suspicion. Laws such as these not only hurt the individuals who live in fear of being jailed for speaking a HL, they weaken the entire nation by promoting the squandering of valuable linguistic resources.

Despite these and other unfavorable policies in the USA (e.g., the No Child Left Behind Act) and elsewhere, HL speakers and HL programs of some sort are likely to carry on. Indeed, as Hornberger (2005) notes, the “contested and ever-shifting” meaning of HL is “the surest evidence of the adaptability and long-term survival of heritage languages in our ever-changing world” (p. 608).

High-Stakes Language Testing

ANTONY JOHN KUNNAN

Introduction

Definition

Whether a test is considered high stakes or not depends not on the testing instrument per se but whether the test is used as the main basis for decision making for a major career path or life changing event. In other words, when decisions based on the interpretation of test scores or evaluations (of a single test) can lead to consequences for test takers, and when these consequences radically alter test takers' major career path or life event, such tests are termed high-stakes tests. For example, in all modern societies, there are high-stakes tests, such as high school graduation tests, college undergraduate entrance tests, university graduate or professional degree entrance tests, professional licensing tests (for medical doctors, nurses, lawyers, pilots, architects, musicians, etc.), employment tests, and immigration and citizenship tests. In these tests, score interpretations provide distinctions such as pass or fail, high or low grades, competent or not competent, and so on. Such categorizations can lead to serious consequences for test takers and therefore these tests are often called high-stakes tests.

High Stakes for Whom?

It is obvious that test takers face pressure in high-stakes tests to perform well. This means they have to know the subject matter well and conditions of the test (particularly in terms of the test tasks, sections, speededness, etc.), use appropriate test-taking strategies, and respond to test tasks efficiently in the time allotted. All this is extremely important as life and career-changing decisions may be made based on a single high-stakes test score. But not all high-stakes tests turn out to be high stakes for test takers. For example, in the United States under the concept of school accountability in the No Child Left Behind Act, there is no negative impact of poor performance on the students themselves. However, school principals and teachers are under pressure to improve their students' scores annually, because if their students do not improve, school managements could be changed, teachers may lose their jobs, and accreditations may be revoked.

In other cases, not all test takers in high-stakes tests put pressure on themselves to perform well and to get the desired benefit. For example, if a test taker who takes a high school graduation test (typically considered a high-stakes test) does not care about the outcome (and therefore does not prepare or take the test seriously), then the test may not work as a high-stakes test for him or her because of the low investment in it. At the other end of the stakes spectrum is a low-stakes test such as a class quiz that is not going to have any impact on a test takers' life or career but, if a highly motivated student in school or college, or an adult in a hobby course takes such a test very seriously he or she might put himself or herself through the same pressure situation as in a high-stakes test.

High-Stakes and Standardized Tests

Many high-stakes tests are also large-scale standardized tests which are administered to large groups of test takers in centralized locations (of the paper and pencil variety) and in standardized conditions (examples, parallel forms of tests, uniform administrative measures). This is typical of high school graduation tests or college or university entrance tests, professional licensing tests, or employment tests. Such standardized tests, typically based on content and performance standards, are widely used mainly because of the convenience associated with administration, scoring, and reporting. But in some contexts, high-stakes tests are not administered on a large scale or are not standardized; examples include high-stakes tests for immigration or citizenship.

Examples of High-Stakes Tests in Schools and Universities

High-stakes tests are most common in schools and universities around the world either as school-level graduation tests (or school-leaving or exit examinations) or as university entrance tests. Three such tests are described below.

The French *Baccalauréat*

The French *baccalauréat*, often known as *le bac*, has more than a 200-year history. Established by Napoleon Bonaparte, the *baccalauréat* is an examination taken by students in their final year of high school (known as the *lycée*) to demonstrate their achievement in school subjects so that based on the examination results students can be placed into university and the *grandes écoles*. When the *baccalauréat* was first designed, it was an oral examination of letters and humanities in Latin and Greek; today, it has evolved into a complex set of examinations of three types: the first type of exam is the *general* exam which has three series: sciences, economics and social sciences, and literature. Then there is the *baccalauréat technologique* and *baccalauréat professionnel*. The exam series is large scale and administered on the same time and day to all test takers in the country. The questions require essay-type responses and could take about 20 hours of testing time depending on the number of classes taken by the students. Successful passage of the exam series is considered completion of the French secondary education.

The CAHSEE

The California High School Exit Examination was recently introduced largely due to the federal mandate under the No Child Left Behind legislation. All high school students in California need to pass this exam in mathematics and English in order to receive a school-leaving diploma. According to the California Department of Education, the purpose and content of the CAHSEE is to improve achievement in public high schools and to ensure that students who graduate from public high schools can demonstrate grade level competency in reading, writing, and mathematics. Similar school-leaving diploma examinations are being introduced in many states in the United States.

The TOEFL

The Test of English as a Foreign Language, developed and administered by the Educational Testing Service, Princeton, is arguably the most well-known large-scale language assessment in the world. The TOEFL has become mandatory for non-American and non-Canadian non-native speakers of English applicants to undergraduate and graduate programs in United States and Canadian English-medium universities. Although the test has become

popular worldwide, the content and structure remained more or less the same over three decades. In the 1990s, a revision project began with TOEFL staff and the Committees of Examiners and Researchers with the intention of revising the TOEFL to include more communicative constructed-response tasks, direct assessments of speaking and writing, integration of skills and modes, more diagnostic information to score users, and the possibility of computer delivery. Given the high-stakes nature of the TOEFL, the revision process was deliberate and long. The Internet-based TOEFL that is administered worldwide today is the result of these revision efforts.

Examples of High-Stakes Tests in the Workplace

High-stakes tests are becoming increasingly popular in the workplace. These assessments are used for screening of applicants for employment and promotion to higher levels in professions that require specific abilities. Examples of this type of assessment include assessment for civil service, health and business professionals, language teachers, court interpreters and translators, tour guides, and air traffic controllers. Here is a description of a few such tests.

Chinese Imperial Civil Service Examination

It can be argued that the earliest known high-stakes tests were the Chinese Imperial Civil Service examination system instituted in China as early as the Han Dynasty (202 BC), continued during the Ming and ending with the Qing emperors in 1905—the longest, almost continuous, examination system, at 1299 years. These examinations were supposedly created to reduce the power of the aristocracy and create a bureaucratic class that was obedient to the emperor. They were promoted and interpreted as a way of identifying merit and capability, and offering equal opportunity thus making social mobility possible. These examinations, which were held at the district, prefectural, provincial, metropolitan, and the palace levels, were in spoken Mandarin (the official spoken dialect) and written classical Chinese. The examinations tested knowledge of the classics from the *Five Classics* and the *Four Books*. Thus, classical erudition, historical knowledge, literary style, poetry, the esoteric art of calligraphy, and the infamous rigid, formulaic parallel-prose style of the eight-legged essays were considered the symbols of the Confucianized gentry-officials. However, left out from the examination pool were large classes of individuals whose parents and families did not have the means of allowing their sons to prepare for the examinations instead of working in the fields. Additionally, the use of Mandarin as the spoken language of the examinations and the use of archaic written classical Chinese privileged the Mandarin-speaking northeast but excluded other geographical regions of China.

The TOEIC

The *Test of English for International Communication*, developed and administered by Education Testing Services, Princeton, assesses everyday English skills of people working in an international environment. It traditionally consisted of listening and reading comprehension sections in a two-hour 200-item multiple-choice test. More recently, it introduced speaking and writing sections which are optional. The test is designed to reflect actual English language use in the workplace although no specialized workplace language is required to be successful in the test. Many international employers and agencies use the test for employment or promotional purposes.

Other Tests

Many current workplace related tests for civil service, health professionals, business, and tourism around the world can be considered high-stakes tests as they are sometimes the only measure of language proficiency. A few examples include the former *Occupational English Test* used for immigrant health professionals in Australia, the *Canadian English Language Benchmark Assessments for Nurses* designed to assess the communication skills of internationally educated nurses whose first language is not English, Cambridge ESOL's *Business Language Testing Service* designed to assess business communication in English, French, German, and Spanish and the *Business English Certificates* at three levels (preliminary, vantage, and higher) which are linked to the Common European Framework of Reference for Languages.

Examples of High-Stakes Tests for Immigration and Citizenship

In more recent times, high-stakes tests have begun to enter the context of immigration and citizenship. Many countries require applicants to take a standardized language assessment in the dominant language of the country they wish to immigrate to or of which they want to become a citizen. Some of the countries that have citizenship (or naturalization) tests include the Australia, Canada, Estonia, Germany, Korea, the Netherlands, United Kingdom, and the United States. A few of these tests are described here.

The US Naturalization Test

Although Naturalization Acts from 1790 onwards have controlled and restricted immigration and citizenship, it was the Immigration and Nationality Act of 1952 that enshrined both the English language and the history and government requirement. This Act required applicants for citizenship to demonstrate their ability to *speak, write, and read English and to demonstrate their knowledge of US history, principles, and form of government*.

Until the late 1980s, this requirement was managed by a variety of immigration courts or immigration examiners. The first US Naturalization Test was designed and administered in 1991. But there were many problems with the test. For example, examiners used different sentences for reading and writing, different content for listening and speaking, different levels of difficulty in the sentence writing, unknown passing criteria, and the history and government questions encouraged memorization of discrete facts with little understanding of the material (see Kunnan, 2009, for more details).

Due to these problems, the test was redesigned. The new test, which has been in operation from October 2008, has the following format: (a) applicants would have three chances to read and write a sentence in English based on a vocabulary list, (b) sentences for reading and writing would cover US history and civics, (c) applicants' answers to questions normally asked about their application (N-400) during the interview would form the speaking test. The redesigned test was expected to address the concerns raised with the old test. But so far, all indications are that the redesigned test is no better than the old test as it still requires much memory of facts and figures, very little English language proficiency, and shows continued variability in test items between examiners. This high-stakes test continues to remain a hurdle in the naturalization process for applicants whose first language is not English.

German and Estonian Tests

Germany and Estonia are two countries that have recently enacted legislation that offers citizenship to its residents. In the case of Germany, ethnic Germans (*Aussiedler*) from the

former Soviet Union and other Eastern European countries are granted the right to resettle in the Federal Republic of Germany. But since 1996, prospective *Aussiedler* and their family members have been subject to a German language test that is administered by an immigration examiner. In Estonia, after breaking away from the Soviet Union, the government wrote laws to make the Estonian language the sole official language and required basic Estonian language for Estonian citizenship. The impact of this policy is that a significant percentage of the Russian-speaking residents of Estonia (particularly, the older generations) are likely to be disenfranchised due to the Estonian language requirement. Thus, such high-stakes tests are used by governments to implement and enforce their immigration and citizenship policy.

Major Criticisms and Possible Safeguards

In general, large-scale high-stakes university, college, and workplace (and some immigration and citizenship) tests are often criticized on many grounds especially when these tests impact different groups of test takers, but many safeguards that can eliminate or reduce the disadvantages of high-stakes testing are available. First, one of the sharpest criticisms of high-stakes tests, that they are used for decision making without any additional information, can be blunted if the various stakeholders (score users like admissions officers, employers, citizenship, and immigration examiners) make decisions using many different pieces of information (such as course grades, recommendation letters, job interviews, etc.) and do not rely only on scores from high-stakes tests.

Second, stakeholders (mainly test developers and score users such as admission officers or employers) ought to conduct studies to show that the tests not only have the appropriate qualities but that the consequences of the tests' scores and decisions made based on them are beneficial to test takers, the community, and society in general. If tests are having a detrimental effect on the test-taking community, then more scrutiny of the test would be necessary. In other words, the welfare of the community should be one of the main considerations in using such tests.

Third, necessary systematic validation research studies ought to be conducted by the test development agencies to show to the test users (test takers, test score users, and other consumers of test information) that the tests, their score interpretations, decisions, and related claims can be defended. In fact, these tests need to meet the highest standards of test development, test score interpretation, and decision making. This will go a long way to demonstrate to the stakeholders and the public that the tests are in fact appropriate measures and therefore decisions based on the test scores will be useful and beneficial to the test-using community (see Tindal & Haladyna, 2002, for a discussion of related issues).

Fourth, comprehensive test evaluations need to be conducted on a regular basis for the particular purpose for which the tests are being used. These evaluations need to be based on established standards such as the APA, AERA, and NCME (1999), and include deliberative forums (with policy makers, test developers, test takers, and community members) as recommended by Heubert and Hauser (1999).

Fifth, an independent oversight body that has the authority and responsibility to review tests, test reports, research studies that defend the claims of tests, and overall usefulness of tests could ensure that tests are beneficial to the community (see Madaus, Haney, Newton, & Kreitzer, 1997, for more on this topic).

Sixth, test takers who are unable to take part in high-stakes tests ought to be given alternative assessments so that their career and life chances are not diminished because of the nature of the tests they are required to take. This obviously applies to test takers with disabilities but also to test takers who are expected to take such tests in their second or third languages or in unfamiliar test conditions.

Finally, government (often encouraged by private agencies) need to avoid legislative mandates that violate professional testing and evaluation standards so that new tests that are developed and launched are not in conflict with established ethical and professional practices.

Conclusion

Although high-stakes tests might be useful in many contexts, stakeholders need to understand the limitations of these tests and use multiple sources of information in making decisions on test takers. In addition, the safeguards presented in the previous section regarding conducting research studies and complying with current testing standards are both critical steps in addressing the many criticisms of high-stakes tests. The safeguards are critical as high-stakes tests are here to stay and we have to learn to use them in the best way we can. As Cizek (2005) puts it, “High-stakes tests: we don’t know how to live with them, we can’t seem to live without them” (p. 50).

Historical Development of Language for Specific Purposes

SUE STARFIELD

Learning and teaching a language for specific rather than general purposes is an approach that began to develop after World War II and has shown continued growth since then, both theoretically and methodologically. This entry focuses on the 1960s–1980s when the fledgling movement began to make a substantial contribution to the field of language learning and teaching. In a survey of the emergent field, Strevens (1977, p. 146) identified what he termed “special purpose language teaching” as being part of a “major, world-wide educational tide of change.” Robinson (1980) notes that the first conference devoted to language for special purposes (LSP) teaching was held in 1969. Initially, LSP referred to language for special purposes, although much of the work being done was, in fact, in the area of English for special purposes (Robinson, 1980). According to Robinson, the term “specific” soon replaced “special” as special was thought to put the emphasis on restricted languages rather than on the specific purposes of the learner and the range of resources the learner might need to access. The LSP learner was not, therefore, learning the language for general educative purposes or for the study of literature in which the language was the subject matter of the course, but rather as a means to the “acquisition of some quite different body of knowledge or set of skills” (Robinson, 1980, p. 6). Thus, from early on, context and content became key issues in LSP pedagogy: in what context would learners be using the language skills and what content would they need to access through the language? Similar approaches to foreign-language teaching were being adopted by other languages; *le français fonctionnel* (Vigner, 1980) was developed as a reaction to audio visual methodologies and traditional grammar-focused teaching under the influence of communicative approaches to language learning and teaching. While LSP was intended to meet the communication needs of rapidly industrializing nations and overcome local barriers to communication by promoting “global” languages such as English or French, we now know that this was often at the expense of local languages.

This entry’s focus is, however, on ESP as its development essentially parallels developments in other languages. For many EFL educators, ESP was perceived and portrayed as a radical, modern, more scientific departure from previous approaches. It was seen initially to concentrate more on reading and less on speaking and writing; to use authentic texts from the specific fields learners were to engage in; to require a degree of communication between language teacher and subject specialist; and, in the main, for the syllabus and teaching materials to be based on notional, functional, and communicative criteria that would help learners meet the communicative needs of their chosen field of practice (see Strevens, 1977).

The origins of this approach cannot be separated from the enormous social changes and massive economic development that occurred after 1945, in what has been called the third wave of globalization (Robertson, cited in Kumaravadivelu, 2006), as Europe struggled to rebuild itself and newly independent Asian and African countries sought to modernize. In line with the modernization agenda, LSP was seen as more efficient, being targeted to the specific needs of the learners in workplace or academic settings. The rise and rise of multinational capitalism during this period also encouraged the development of LSP teaching,

seen as a means of improving workplace productivity and facilitating trade. Simultaneously, ideologies of progress, and the desire to facilitate international communication, student exchange, and understanding were supported by organizations such as the United Nations in the hope of preventing future world wars and created a fertile terrain for LSP development. In Europe, the work of the Council of Europe to promote foreign-language learning across what was eventually to become the European Union led to influential developments in needs analysis and syllabus design, which will be discussed further below. Again the agendas of trade and commerce and greater understanding between nations were intertwined.

These somewhat contradictory aims and intentions are at the heart of LSP and are the source of some of the critiques that have arisen more recently (see, e.g., Pennycook, 1997; Benesch, 2001). Benesch documents what she calls an “unofficial history” of ESP in which large-scale ESP development is seen to be driven less by goals of global communication and understanding but more narrowly by the growth of US oil interests in the Middle East from the 1960s onwards. She illustrates this view by quoting from a presentation by Strevens at a 1971 conference on “Adult English for National Development” held in Beirut: “The profession . . . can now say . . . to the oil industry or to a shipping firm or even to a government . . . describe accurately the precise achievement in English that you require, we can “engineer” a system that will reach this target” (Strevens, 1971, cited in Benesch, 2001, p. 30). Organizations such as the British Council, the Ford Foundation, and the United States Information Agency (USIA) were also instrumental in promoting ESP in particular and contributed to the establishment of English as the dominant language of science and technology and commerce (Hutchinson & Waters, 1987; Benesch, 2001). Robinson (1980, p. 3) notes that much ESP work in the period prior to 1980 was being carried out at sites such as the Regional English Language Centre in Singapore; the University of Khartoum, Sudan, which produced a publication called *English for Special Purposes in the Middle East and North Africa (ESPMENA Bulletin)*, and the University of Chile in Santiago, underlining the global spread of ESP. Many of the early proponents of ESP such as Swales, Dudley-Evans, and Robinson developed their ESP approaches in the newly independent states, often working on British Council funded projects, while much of the early dissemination of their work and the work of others in the new field was through British Council publications in the ELT Documents series (see Robinson, 1980, for a comprehensive bibliography and Swales, 1985).

The link to the postcolonial context is explicit in *The Linguistics Sciences and Language Teaching* (Halliday, McIntosh, & Strevens, 1964), an influential text that set out a pedagogical agenda for LSP based on functional linguistics, in particular the study of register. The book’s title promised a more scientific approach to language teaching. The authors argued that “only the merest fraction of investigation has yet been carried out into just what parts of a conventional course in English are needed by . . . power station engineers in India, or police inspectors in Nigeria; even less is known about precisely what extra specialised material is required” (Halliday et al., 1964, p. 189). While identifying need and context as important categories, the task of the linguist was, in their view, to carry out “detailed studies of restricted language and special registers” based on “large samples of the language used by the particular person concerned.” The importance of what came to be called “authentic” texts—that is, texts that learners were likely to encounter in their work or study situation—is also evident in their thinking. Halliday and colleagues’ emphasis on specific sublanguages or registers was seminal to the development of inter alia the many LSP and ESP subfields that are still studied and taught today—for example, English for medical purposes; English for law; English for nursing; English for science and technology; and English for academic purposes in addition to numerous occupational sublanguages such as English for business or occupational purposes and vocational or workplace English.

As LSP grew out of concerns to provide an approach to language learning and teaching that was distinct from “general” purpose or traditional literature or humanities-based language teaching, it is not surprising that its initial focus was on language for science and technology. As Benesch (2001, p. 5) points out, this trend was supported by a “postwar boom in funding for sciences and technology by the United States and the United Kingdom [that] included subsidies for English language teaching.”

English for science and technology (EST) research was influenced by register analysis and took the form of frequency studies of lexical items and grammatical features of science texts. Huddleston’s (1971) study of a 135,000 word corpus of scientific English looked for clause- and sentence-level patterns. Early approaches to ESP pedagogy reflect the influence of what Swales (2000, p. 60) has called a “simplistic relationship between linguistic analysis and classroom activities.” According to Swales (1985, p. 17), the first English for specific purposes textbook was Herbert’s (1965), *The Structure of Technical English*, based on a “serious and detached investigation into the characteristics and the language found in science and engineering written texts.” Textbooks developed on the basis of register analysis include Ewer and Latorre’s (1969) *A Course in Basic Scientific English*, from a study of 3,000,000 words of modern scientific English (Benesch, 2001, p. 5). Criticisms of this approach included the following: analysis was confined to sentence level; the restricted range of grammar and lexis provided an insufficient basis for a textbook on English for science and technology; reading passages lacked authenticity; the approach focused overly on form at the expense of meaning and communication; and whether special registers could, in fact, be clearly identified (Robinson, 1980; Dudley-Evans & St John, 1998).

Although much critiqued in the later literature, it is interesting to note, as Paltridge (2009) points out, that the development of sophisticated software has led to a resurgence of interest in and greater development of the potential of register analysis for our understanding of both written and spoken discourse.

Partly as a response to the difficulties experienced with register analysis, and under the influence of communicative approaches to language teaching and theoretical frameworks such as speech act theory and functional linguistics, applied linguists began to examine texts beyond the level of the sentence in terms of their overall discourse structure and their rhetorical purpose or communicative function. The emphasis shifted to language use and how meaning was produced in the performance of communicative acts. Early exemplars of this approach include *Industrial English* (Jupp & Hodlin, 1975), which explicitly adopted a functional approach to analyzing the language needed by factory workers in the UK, signaling a clear intention to move away from the linguistic/structural syllabus to what people do with language in the workplace. In the USA, Lackstrom, Selinker, and Trimble (1973) examined organizational patterns in EST texts, particularly at the paragraph level; these were assumed to differ significantly from those of other registers. The nine-volume *English in Focus* series, edited by Allen and Widdowson between 1974 and 1980, featured textbooks in areas such as physical science, mechanical engineering, medical science, education, social science, and biology. The series follows a rhetorical–functional approach based on Widdowson’s (1979) view that scientific discourse can be seen as a set of rhetorical acts such as giving instructions, defining, classifying, exemplifying, and so on. This early interest in texts and the relationship between form and function (communicative purpose) laid the foundation for the development of studies of genre and the concept of discourse community, which have become central to ESP (see Swales, 1990).

These early approaches to ESP were based on the belief that identifying the specific variety of language or discourse functions of the particular domain of future study would meet the learners’ communicative needs and sustain student motivation. As most ESP learners were adults, they were also assumed to have more clearly identifiable needs than younger learners. Needs analysis was used to carry out target situation analysis to better

specify the communicative language functions required within the specific context and develop appropriate syllabus content (see Hutchinson & Waters, 1987; Benesch, 2001). Munby's (1978) *Communicative Syllabus Design* can be seen as an attempt to provide a more theoretically informed and systematic approach to needs analysis through detailed lists of microfunctions which the ESP practitioner would need to complete prior to commencing syllabus development. Although largely unimplementable in the real world of ESP, and discounted today, the approach had the merit of placing needs analysis, situation, function, and context at center stage in LSP and alerting LSP practitioners to the multiple variables that needed to be considered when adopting a communicative approach. The more sophisticated needs analyses approaches in use today can be seen to have evolved in part as a reaction to Munby's work.

Munby's needs analysis model was a precourse analysis that the course developer carried out once, prior to implementation, and did not take into account institutionally available resources. In contrast, Richterich and Chancerel's (1977) influential approach to needs analysis (developed for the Council of Europe to identify the needs of adults learning a foreign language) is an ongoing process, not a one-off event carried out prior to the commencement of a course. In this approach, the learner, the educational institution, and the employer separately identify their needs, which may include available resources; objectives; curriculum; or teaching methods. Methods were largely quantitative and included surveys and questionnaires and content analyses but also nondirective interviews, language-attitude scales, and job analyses.

Hutchinson and Waters (1987) developed a critique of what they called the "language-centered approach" (p. 54) to target situation analysis which, while using subject area texts, simply produced lists of linguistic features to be learned and often led to materials that were demotivating for students. Hutchinson and Waters's significant contribution was to focus on the learning needs of the learner: what the learner needs to do in order to learn. They thus directly engaged with the question of motivation and with theories of learning. They argued that teachers need to focus on the underlying competencies and learning skills that lecturers assume students will have and will enable them to reach the target performance, rather than concentrating simply on linguistic features of specialized texts. In arguing against the existence of specialized varieties of English, Hutchinson and Waters can be seen to be in favor of what has become known as a "common core" approach rather than a highly subject-specific one, which obviously has implications for the role of the ESP teacher (Dudley-Evans & St John, 1998).

Widdowson (1979) further attempted to define the role of the ESP teacher in a way that would circumvent some of the difficulties experienced by essentially humanities-trained teachers of English. His theoretical position was also influential in materials development at the time. He argued that the underlying processes of scientific inquiry were universal, that they existed independently of their realizations in different languages, and that students entering higher education would already have been initiated into these concepts and procedures as they were realized in their own language. What the students did not know was how to communicate this knowledge in English. According to this view, the role of the ESP teacher was therefore to help the students to communicate in English the knowledge of science they already had. However, those working in contexts where students' knowledge of science was not well established due to poor schooling, and where teachers could not rely on students' prior knowledge, found that many of the textbooks which were based on the rhetorical-functional approach as conceptualized by Widdowson (see Robinson, 1980; Swales, 1985; Starfield, 1990) did not meet their students' learning needs. Starfield (1990) discovered that her South African students had not been taught science at high school in their first language at a level that would have enabled them to acquire the universals Widdowson describes and had therefore to acquire both English and science at

university. English-language teachers struggled to respond to the students' multiple learning needs, which often led to the development of team teaching—in which subject specialist and language teacher collaborated to varying degrees—and other contextualized approaches to instruction in many parts of the world (Kotecha, Rutherford, & Starfield, 1990; Dudley-Evans & St John, 1998). ESP practitioners also found that they needed to either significantly adapt materials produced elsewhere or develop their own local materials to meet local needs.

The degree of subject area knowledge required by language teachers and their relationship with content-area specialists and specialized texts are issues that continue to be posed in LSP. Whereas Kotecha, Rutherford, and Starfield (1990) and Johns and Dudley-Evans (1980) and others' realization that language needed to be embedded in content and context in some way for students led to team-teaching, language and content integration, and linked courses (Benesch, 2001), others such as Spack (1988) saw the role of the language and writing teacher as being about teaching general skills of inquiry and principles of rhetoric, leaving subject-specific conventions to subject specialists. The debate has continued, with Hyland (2002) again posing the question as to how specific ESP needs to be and how much content-area knowledge the ESP teacher or applied linguist requires. While Hyland argues for specificity as the cornerstone of ESP, he does acknowledge that real institutional constraints may hamper this. Tarone, Dwyer, Gillette, and Icke, writing in 1981, stressed how essential was the subject specialist's contribution to their study of the rhetorical structure of two astrophysics texts.

In a recent overview of ESP developments through the last decade of the 20th century and the early years of the 21st century, Belcher (2006, p. 135) notes that there would probably be agreement that "[n]eeds assessment, content-based teaching methods, and content-area informed instructors have long been considered essential to the practice of specific-purposes language teaching." Although frameworks for interpreting these "distinguishing features" of ESP have continued to evolve, and the initial vision of the language teaching profession's task adopted by Halliday et al. (1964) has been shown to be more complex than these authors could have envisaged, the similarity of these concerns and those identified by Strevens in 1977 point to a continuity of purpose within specific-purposes teaching.

Historical Development of Literacy Research

NICOLE M. MARTIN, MARIA SELENA PROTACIO, HSUAN-YI HUANG,
NAI-CHENG KUO, AND DOUGLAS K. HARTMAN

Introduction

The history of literacy research is like a series of slow, undulating waves. Just as a wave reaches its crest, it wanes and another overtakes it. The ebb and flow of literacy scholarship follows a similar pattern. In this entry we focus on the *topical* shifts in literacy research during the last 140 years by using the language arts as our analytic frame (i.e., reading, writing, speaking, listening, viewing, and visually representing; National Council of Teachers of English [NCTE] and International Reading Association [IRA], 1996).

Six overlapping periods of literacy research are outlined below. Beginning with the study of physical processes associated with literacy (1870s–1920s), the succession of overlapping topics include the effectiveness of literacy instruction (1910s–1980s); the cognitive modeling of literacy processes and development (1970s–mid-1980s); the development of literacy in social, cultural, and linguistic contexts (early 1980s–early 2000s); the impact of policy on literacy instructional research (late 1950s–early 2000s); and the expansion of literacy across media and spaces (1950s–2010s). Literacy research in each of these periods focused on varying aspects of the six language arts.

The transitions from one period to another were set in motion by common undercurrents, such as shifts in theoretical and political winds, inexorable methodological movements, and technological surges in the media. The recurrent theme across all six periods is the subsumation of *speaking*, *listening*, *viewing*, and *visually representing* into *reading* and *writing*.

Literacy Processes (1870s–1920s)

The dawning of research on literacy focused largely on the physical processes of reading, writing, speaking, and listening. The earliest research on literacy was focused almost exclusively on reading.

Reading

Studies published during this period focused on the physical processes of reading, such as eye movements, perceptions during reading pauses, visual perception, inner speech, reading fatigue, reading rates. For example, Dodge's (e.g., 1899) early research investigated the perception, movement, and reaction of the eye during reading. And Huey (1898, 1900, 1901) as part of his dissertation at Clark University examined eye movements using an ingeniously designed apparatus. He later published a classic tome on *The Psychology and Pedagogy of Reading* (1908) which synthesized all the extant reading research in print on both sides of the Atlantic. A few studies during this period, such as Thorndike's (1917) study on "Reading as Reasoning," presaged a later move to study the cognitive processes of reading.

2 HISTORICAL DEVELOPMENT OF LITERACY RESEARCH

Writing

A small number of studies focused on the physical and technical processes of handwriting, such as its neurological underpinnings and issues of speed, legibility, accuracy, perception, muscular control, motion, and spelling. For the most part, writing instruction during this period was rooted in the formalist tradition of mastering penmanship, grammar, usage, and style through prescriptive and formulaic genres like the five-paragraph theme, and writing research did not stray too far from this ideological leash. Even with the advent of the typewriter, research largely focused on the physiological aspects of hammering print on paper. While the earliest signs of writing-as-a-process appeared in the 1910s, empirical research on writing-as-a-process did not emerge until half a century later.

Speaking

During this period, research on speaking focused on the physiological processes of the oral reading act. Because reading was largely enacted as an elocutionary or performance practice, the new science of pronouncing words with force, clarity, and correct intonation examined the underlying physical mechanisms to identify principles that could inform instruction in oral reading. Textbooks throughout the 1800s contained both “readers” (i.e., the initial and middle texts in the series) and “speakers” (as the later, elocutionary texts in the series were called), with the *McGuffey Readers* serving as the archetypal textbook series based on this blend of readers and speakers. During the latter part of the 1800s, the physiological research on speaking made its way into the instructional methods and materials of a new generation of speaker texts, such as McGuffey’s *New Juvenile Speaker* (1860). The research on declamatory speaking during this period even extended to studying the physical processes of gesture that related to the spoken word, known then as “visible action in speech.”

Listening

Research on listening was nascent during this time period. Two journals served as the primary venues for physiological research on listening and hearing: *The Volta Review* and the *American Annals of the Deaf*. One of the earliest education-related studies (Erickson & King, 1917) compared the recall of information presented to students visually and aurally. With radio emerging as a medium for entertaining, informing, and educating the masses, academic and instructional interest in listening comprehension gained widespread traction when several seminal pieces of scholarly work were published in the 1920s.

Literacy Instruction (1910s–1980s)

The topics and focus of literacy research enlarged considerably from the 1910s to 1980s. Reading and writing research turned in a number of directions, while speaking and listening research gradually rose in visibility, only to later disappear.

Reading

Reading research greatly expanded between the 1910s and 1980s. Animated by ideas and philosophies from many disciplines, two waves of research livened the move to optimize instruction. From the 1910s to the 1930s, researchers studied text-centered instructional approaches, such as drill and practice and integrated high school content area lessons (e.g., Robinson, Faraone, Hittleman, Unruh, & Fitzgerald, 1990).

After a lengthy period where behaviorist tenets prevailed, a flood of reader-centered instructional studies appeared from the late 1950s to the 1980s. The studies investigated such topics as

- reading comprehension instruction (e.g., text structure analysis, story grammars),
- code- and meaning-based approaches to learning to read,
- college reading,
- critical reading,
- comparative reading,
- the effects of technology on reading growth,
- graphic organizers,
- non-traditional early reading methods,
- illustrations,
- imagery generation,
- metacognitive training,
- semantic mapping,
- social learning techniques, and
- visual presentation methods.

Writing

Like studies of reading instruction, the writing research also shifted direction. Until the waters stilled in the 1940s, researchers focused on topics such as the writing of texts (e.g., writing words; Hamilton, 1920) and out-of-school writing (e.g., Hildreth, 1936). When a new wave of studies appeared in the 1970s, writer- and school-focused studies washed ashore. Researchers investigated topics such as children's emergent writing, teachers' instructional practices, and genres in academic writing.

Speaking

Research on speaking was quiescent for much of the period. When basic research on human speech appeared in the late 1960s, an upsurge in instructional research followed. For example, researchers studied oral language in classrooms, children's language use, young children's peer interactions, and classroom language practices.

Listening

Research on listening was also in the background for many years. Before the 1950s, less than a handful of studies focused on listening and instruction (Anderson, 1952). Beginning in the 1950s, insights from listening development informed a wave of listening instructional studies. Researchers studied many instructional topics, such as the role and outcomes of school-based listening instruction (e.g., audio-taped readings, advanced organizers), time spent listening in school, critical listening, and the nature and effects of classroom interactions.

Literacy Processes and Development (1970s–Mid-1980s)

In the middle of the 20th century, archival journals were filled by new forms of basic research on literacy. A new generation of researchers studied literacy processes and development. They invented and crossed theoretical, conceptual, methodological, and analytic boundaries.

Reading

The building interest in research on basic reading processes (e.g., causes of reading difficulties, reasoning, remembering; Weaver & Kintsch, 1991) stimulated two new and related waves of reading research in the 1970s and 1980s. Researchers studied topics such as readers' strategies, interactions between texts and readers, teacher and student thinking, and

4 HISTORICAL DEVELOPMENT OF LITERACY RESEARCH

neurological reading processes. They also explored developmental trajectories and factors, including reader (e.g., automaticity and phonological awareness) and text variables (e.g., graphics, macrostructure, sentence length). Finally, they developed new models of the reading process.

Writing

Two long-term research movements—which focused on writing development and processes—undulated their way across the writing research scene in the 1970s and 1980s. Preceded by earlier topics of interest (e.g., Hildreth, 1936), researchers

- investigated topics such as the modes of composing and the variables that influence the writing process;
- crafted theoretical models of the writing process;
- examined genres in academic writing;
- explored young children's growth as spellers and writers; and
- called for more studies on the acquisition, nature, and use of writing.

During the 1970s and 1980s, writing research examined the integration of composition and other language arts, by comparing writing to other literacy domains and exploring how these domains could foster children's writing development.

Speaking

Foreshadowed by earlier research (e.g., Petty, 1967) and fueled by a review of the extant literature on speech communication development (e.g., Allen & Brown, 1976), research on speaking surged in the 1970s and 1980s with investigations into the processes of language and children's development. Researchers examined topics such as language-in-use (e.g., peer-to-peer interactions, disciplinary discourse); language rules, systems, and structures; and the functions of language. They also studied patterns (e.g., audience sensitivity) in children's language use and development across different contexts (e.g., arguing, informing, imagining). Finally, researchers started to explore the relationships among speaking and other literacy domains (e.g., reading and writing).

Listening

During the 1970s and 1980s, research on listening was integrated with other domains. In addition to studies of basic listening processes (e.g., individuals' capacities to process oral information, the relationship between listening and intelligence; Foulke & Sticht, 1969), researchers in other literacy domains studied listening processes and development. They examined, for example, connections between listening and reading, and the relationship between listening and school achievement.

Literacy Development in Social, Cultural, and Linguistic Contexts (Early 1980s–Early 2000s)

The emergence of sociocultural and sociolinguistic learning theories marked the beginning of another period of research. The undercurrent of research during this period was the idea that literacy was more than the ability to read and write; rather literacy was intertwined with culture, context, and language.

Reading

In the early 1980s, Heath's (1983) seminal piece, *Ways with Words*, examined how contexts play significant roles in shaping how individuals are exposed to and interact with texts. Running against the earlier current of finding the best way to instruct students in reading, this wave of research highlighted how children's cultural, linguistic, and socioeconomic backgrounds need to be taken into consideration. Researchers during this time examined how children's backgrounds figured into their literacy learning and developed related theoretical frameworks (e.g., culturally relevant pedagogy, culturally responsive instruction, funds of knowledge, and primary and secondary "Discourses"). Researchers also looked at other topics, including classroom contexts and how they impact students' affect and motivation, home literacy contexts and the role that families play in reading development, and the reading processes of second language learners.

Writing

During this period, researchers built upon and refined extant models of writing to improve their explanatory and predictive precision (e.g., Hayes, 1996). For example, they incorporated students' use of cultural resources in their writing. Other research during this time examined writing as a vehicle for personal expression, explored how writing is connected to identity formation, and investigated how dialogue and social interaction influence writing.

Speaking

Researchers added to the literature which explored how speaking or dialects influenced reading skills. They focused on sociolinguistic alternatives in teaching reading to nonstandard speakers and how Black dialect affected performance on a reading test (e.g., Hunt, 1974–5).

Listening

Research on listening explored how instructional activities (e.g., reading aloud) impacted students' listening comprehension and word knowledge (e.g., Elley, 1989; Sinatra, 1990).

Literacy Research in a Policy Context (Late 1950s–Early 2000s)

Federally funded literacy research first emerged in the 1950s–1960s as concerns about educational equality surfaced. During the 1980s, researchers responded to federal funding priorities by increasing their focus on schools' instructional accountability. In the late 1990s and early 2000s, federal funding agendas prioritized questions that closed the achievement gap with designs that met scientific rigor.

Reading

Early influences on federally funded literacy policy came from the *Brown v. the Board of Education* decision in 1954, where the ruling in favor of an egalitarian purpose for education meant that reading for all was a standard to be set, funded, and reached (e.g., McGill-Franzen, 2000; Valencia & Wixson, 2000). Thereafter, many policy initiatives supported educational initiatives that funded reading research, including the National Defense Education Act (NDEA) in 1958, Elementary and Secondary Education Act (ESEA) in 1965, Head Start program in 1965, Bilingual Education Act (Title VII of ESEA) in 1968, and the Education for All Handicapped Children Act in 1975.

Under the NDEA, several large-scale reading research projects such as Project English and the First Grade Studies were established. Under the ESEA, 19 research and development (R&D) centers were created to conduct, oversee, and disseminate research on many educational topics. One of these centers focused exclusively on reading research: the Center for the Study of Reading (founded in 1976 at the University of Illinois, Urbana-Champaign). Another center focused on adolescent reading issues: the National Research Center on English Learning and Achievement (located at the State University of New York at Albany).

In the 1980s, federal policy initiatives shifted toward increased school accountability. Known as the “standards” movement, several successive initiatives developed and used reading standards to hold schools accountable for student learning: the National Commission on Excellence in Education (NCEE) report *A Nation at Risk* in 1983 (NCEE, 1983), the revised ESEA in 1988, the retitled ESEA of Improving America’s Schools Act in 1994 (IASA), and the more recent No Child Left Behind (NCLB) legislation in 2001.

Federal funding priorities shifted to early reading in the late 1990s and early 2000s, for example the National Research Council’s report on *Preventing Reading Difficulties in Young Children* (Snow, Burns, and Griffin, 1998), the National Reading Panel’s review of reading instruction and research in 1997 (www.nichd.nih.gov), President Bush’s Good Start, Grow Smart early learning initiative in 2002, and the US Department of Education programs Reading First in 2001 and Early Reading First in 2005, all stressed early reading instruction.

Writing

The federal policy initiatives that supported writing research were far fewer than those in reading—and sometimes embedded within the reading policy initiatives. The earliest and most visible policy move to impact writing research took shape when the NDEA established the Iowa Writing Project in 1967. Less than a decade later, in 1974, James Gray, his colleagues, and the Bay Area Writing Project established the National Writing Project (NWP) at the University of California, Berkeley. Later, in 1986, the ESEA-funded Center for the Study of Writing (CSW) was founded at the University of California, Berkeley (in partnership with Carnegie Mellon University). The CSW conducted, oversaw, and disseminated research on a range of writing topics.

Literacy Across Media and Spaces (1990s–2010s)

Widespread access to new technologies prompted a shift in focus for literacy research. For instance, the medium for literate activity (e.g., analog to digital; desktop to laptop to handheld) became an important aspect of literacy research.

Reading

The earliest studies examining media use in education were conducted in the 1960s (e.g., Witty & Kinsella, 1962). Subsequently, researchers focused on the effects of television on children’s reading comprehension and language development. During the 1980s and 1990s researchers investigated the effects of media (e.g., film, video, and audiovisual equipment) on children’s reading comprehension and language development.

The expansion of literacy research from static material to dynamic interfaces gained considerable momentum during the 1990s and 2000s. With the development of new digital technologies and software tools, widely accepted conceptions of literacy expanded to include constructs such as spatial knowledge and tool use. New conceptual labels—such as *third space* and *fifth dimension*—migrated into scholarly work to help researchers understand and explain how “new literacies” are enacted with digital tools in a range of spaces

(Coiro, Knobel, Lankshear, & Leu, 2008). The focus of literacy research has also shifted to the study of professional and community spaces where complex, dynamic, iterative, ill-structured, and interactive reading practices occur.

Writing

Writing research began to focus on new types of media (e.g., graffiti) and spaces (e.g., city structures) during the late 1990s. In Conquergood's (1997) study of street literacy, he found that people wrote or drew on locations in a cityscape to release their voices and express their thoughts. He noted that there was no specific rule to interpret graffiti, "Although I have tracked through several graffiti texts in order to illustrate the structural conventions and complexity of this writing system, gangster grammatology exceeds the 'model of the text'" (p. 366). In addition to street literacy, research on composition also became important in understanding the development of writing across media and space (e.g., Mesa, 1997).

Historiography

PAUL KEI MATSUDA

What Is Historiography?

Historiography is the methodology for historical research. In applied linguistics, historical research is a form of metadisciplinary inquiry (Matsuda, 1998, 2005) that seeks to establish knowledge about the field itself—its origins and development as well as the development of various ideas and institutional practices (such as graduate programs, departments, conferences, publications, and research centers). As such, historical research may not contribute directly to the goal of applied linguistics—to address language-related issues that affect language users and uses as well as ideological conditions that surround them. Rather, it provides an understanding of the historical, institutional, and ideological contexts in which disciplinary inquiry takes place, providing the field with a shared sense—albeit multiple and competing—of who we are, where we came from, what we have been doing, and how. This knowledge, in turn, helps members of the field critically assess its current state and consider where it might, could, or should be going. Historical knowledge is also useful in orienting newcomers to the field, such as graduate students and other novice researchers, as well as researchers from other, related fields seeking to understand and contribute to the collective knowledge-making enterprise. Historical research can also provide useful examples of knowledge or practice that are still relevant today; at the very least, it can help avoid reinventing the wheel.

Historical knowledge provided by metadisciplinary inquiry is especially important during the formative years of a field, when it is trying to establish its own identity and legitimacy by establishing its intellectual heritage, by identifying important exigencies, by documenting successes (and failures) in institutionalizing, or by dissociating itself from its predecessors (e.g., Titone, 1968; Darian, 1972; Allen, 1973; Diller, 1978). Once the field is established, existing historical narratives—history written by the victors—begin to circulate and take on the status of orthodoxy, giving rise to *received history*. The received history is often reproduced in the form of chronological literature review in introductory chapters of professional books without the critical examinations that are characteristic of historical scholarship. Historical accounts based on received history are often strikingly similar to one another, and they do not often provide justifications for periodization (deciding when certain historical periods began and ended), for taxonomies implicit in the historical narrative, or for what gets included or excluded. In other words, received history is history without historiography.

The existence of a received history can be an indication of how well established a field is, and it can be useful in providing a sense of stability and coherence, giving novice researchers something to grasp as they enter the field. Ultimately, however, it is a false sense of stability and coherence because an academic field is often diverse and always in flux, and there are multiple and competing perspectives, reflecting the situatedness of various researchers (Atkinson, 2000; Kaplan, 2000). The most serious problem of received history is that it tends to legitimize dominant axiology, epistemology, and methodology while excluding alternative perspectives—a different interpretation of the present based on a broader understanding of the past. This situation, if left unexamined and unchallenged,

2 HISTORIOGRAPHY

can in turn lead to intellectual stagnation which discourages critical dialectics and generation changes, and eventually to the shortage of new research questions and the demise of the discipline. Disciplinary historians' work, then, is not only to generate new historical knowledge but also to constantly reexamine and revise existing knowledge, providing alternative perspectives and resituating the historical knowledge in the current dynamics of the discipline (e.g., Musumeci, 1997; Matsuda, 2006).

The intellectual work of disciplinary historians includes the following (North, 1987, p. 71):

1. Identifying the Problem
EMPIRICAL STAGE
2. Identifying Relevant Texts
3. Searching for Relevant Texts
4. Assembling and Validating Relevant Texts
INTERPRETIVE STAGE
5. Seeking Pattern(s) in Texts
6. Explaining the Pattern(s): Creating a Narrative
7. Relating New Narrative to Existing Narratives: The Communal Dialectic
8. Dissemination to a Wider Audience

What distinguishes serious historical inquiry from mere chronological literature reviews is the level of rigor by which historians evaluate historical evidence and interpretations to establish and critique historical facts and narratives. That is, serious historians need to be aware of the socially constructed nature of historical knowledge, which is always contingent and open to reinterpretation.

Historical Data

Historical research is predominantly qualitative, hermeneutic (i.e., interpretive), and narrative in nature (Casanave, 2005), although quantitative data can also be used to document trends and developments. (Examples of quantitative data may include the number of applied linguistics doctoral programs, the number of multilingual students in a school system, the number and percentage of sessions on a certain topic at a conference, and the number of publications on a given topic.) Historians consider all available sources of data (i.e., historical evidence) to establish *historical facts* (or disestablish existing ones) and examine how they fit into a large and complex network of historical knowledge to construct plausible historical narratives (or problematize existing ones).

Sources of historical data can be broadly classified into primary and secondary. *Primary sources* provide evidence to establish historical facts—people, places, things, and events, as well as how those elements were interpreted and represented at the particular historical moment under investigation. *Secondary sources* are representations of historical facts as well as interpretations and analyses of those facts, their interrelationships, and their implications. Primary sources are analogous to original data collected by the researcher in an empirical research project, while secondary sources correspond to sources cited by the researcher to construct the research problem or knowledge gap, to corroborate the findings, to support an interpretation of data, or to indicate alternative perspectives.

In metadisciplinary history, the boundary between primary and secondary sources is not always clear cut. For example, Kelly's (1969) *25 Centuries of Language Teaching*, which provides a historical analysis of various language teaching methods since antiquity, is a secondary source to contemporary historians of language teaching in many cases because it represents existing historical knowledge about language teaching. Historians may use

this source to identify an existing interpretation of historical developments or to point out the limitations of the history as represented by Kelly. Alternatively, it can be used—alongside other histories produced by his contemporaries—as a primary source to establish how the history of language teaching was represented at the time, revealing some of the values and assumptions of his time. In other words, the distinction between primary and secondary sources is a functional one based on how the source is being used—whether we are examining the history of language teaching through Kelly’s work (as a secondary source) or we are examining his study as part of a historical development (as a primary source).

Historical sources may come in various shapes and forms. In metadisciplinary inquiry—which is a self-conscious inquiry into the history of the discipline by an insider—much of the historical data comes from published texts in the field, such as books, journal articles, conference proceedings, textbooks, and the like. Particularly useful to disciplinary historians are introductions in books and editorials in journals, where values and assumptions as well as the authors’ and editors’ intentions are often made explicit. When the same book is available in multiple editions, the comparison of different editions can provide a glimpse of how a particular concept or subfield evolved over time. Many of the published sources are available at various universities and national libraries, although the availability varies from library to library. When certain documents are not available locally, librarians may be able to help obtain them from other libraries. In many countries, librarians from the researcher’s institution can write letters to another university library requesting access to needed materials. In some countries, such as the United States, librarians can help obtain publications that are not locally available through interlibrary loan or consortia of libraries. Other libraries, such as the British Library, provide document reproduction services to users worldwide (for a fee).

For historical work related to language and education policies (e.g., Hornberger & Vaish, 2008), government documents and court records provide the essential historical evidence related to language legislation, funding, and court rulings. Census data and other sources of demographic information—such as *Open Doors* (Institute of International Education, 2009), which documents the international exchange of students and scholars between the United States and other countries over the years—are valuable in establishing the distribution of language users. Newspapers, magazines, and other periodicals can also provide important information that provides a sense of larger social, economic, and political contexts. TV shows, movies, and other audiovisual materials may also be useful depending on what claim the researcher is trying to support or refute. Unpublished documents or publications of limited circulation, such as manuscripts, conference papers, letters, and e-mail messages, can also prove important sources of historical data that may not be available in published sources. Some unpublished documents have been preserved by database services such as ERIC Document Reproduction Services. In recent years, a growing number of unpublished documents have been made available on the Internet.

Historians can also draw on *archival sources*. An archive is a collection of documents and artifacts preserved by archivists for the purpose of later examination. At many university libraries, archivists collect, select, and preserve documents such as memos written by administrators, in-house publications related to programs, manuscripts, conference and note papers written by notable researchers, and even assignments and student papers. The English Language Institute (ELI) at the University of Michigan, for example, has its own library and librarians who maintain historical documents related to the Institute. Other documents that can shed light on Michigan’s language teaching programs before the ELI can be found at the Bentley Historical Library at Michigan. Since archived documents are usually not available elsewhere, historians travel to specific archives to gain access.

Historians who study a relatively recent historical period may use oral or written history interviews to collect narratives provided by individuals who have lived through particular

historical events to gain their perspectives on how various historical events evolved and what those developments meant to those people. It would be useful, for example, to ask well-established researchers to tell their stories about their involvement in the development of an applied linguistic organization or to recount their perspectives on the evolution of a concept or methodology. Of course many of those recountings happen in their own conference presentations and publications. While those accounts provide rich, insiders' perspectives, the quality of the accounts needs to be carefully evaluated through the processes of internal criticism (see next section).

Evaluating Historical Sources

Historical sources are evaluated through the processes known as external and internal criticism. *External criticism*, on the one hand, is concerned with the credibility of the source itself. When was this source written and by whom? How widely was it circulated? Has this source been edited extensively after the death of the author? For example, the authorship of *Rhetorica ad Herennium*, a Roman rhetorical treatise once attributed to Cicero, has now been widely disputed ([Cicero], 1954). The text can still be useful in understanding a conception of rhetoric during the period, but it is not appropriate if used as a source for discussing Cicero's thoughts on the organization of persuasive discourse. Although these questions may seem less relevant to relatively recent sources that tend to have more reliable records of authorship and other information, the questions cannot be dismissed entirely. For example, published works may reflect the interventions of reviewers and copy editors, distorting the authors' original intentions. Another example is the date of publication; copyright dates are not always reliable as a way of establishing the chronology because publishers sometimes use future copyright dates to extend the shelf life (e.g., a book published in December 1999 may be registered with the copyright date of 2000). In many cases, new ideas, data, and interpretations are introduced into the field first through oral presentations before they appear in print or digitally.

Internal criticism, on the other hand, is concerned with the quality of information and perspective provided by the source. A researcher who is studying the history of applied linguistics at Columbia University might be tempted to cite Darian (1972) to suggest that Columbia was the first university in the United States to offer an English language support program, in 1911. Although Darian does so claim, he does not provide any supporting evidence, and there does not seem to be any other source available to corroborate his assertion; in fact, Kandel (1945) contradicts Darian by pointing out that Columbia was not able to create "special provisions" for international students until 1923 (p. 50). A broader investigation of the history of English language support programs in US higher education (e.g., Matsuda, 1999, 2005) suggests that 1911 happens to be the year that Joseph Raleigh Nelson established his English course for international students at the University of Michigan, a historical fact that has been documented by several sources (Norris, 1966; Allen, 1973; Fries & Fries, 1985) and supported by archival evidence (e.g., syllabi, activities, and student papers available at the Bentley Historical Library at Michigan). It is likely, then, that Darian mistakenly attributed the creation of the first program to his alma mater. The situation may change if further archival research uncovers new evidence to suggest that a similar program was also created at Columbia.

Organizing and Presenting Historical Knowledge

Historical inquiry can take many different forms depending on the purpose, scope, and organization of the project. One approach, known as the *history of ideas*, is to trace the

development of ideas, providing an overview of various layers of meaning attached to a particular one (e.g., Leki, 1991; Ricento, 2000; Thomas, 2004; Berns & Matsuda, 2006). This approach is useful in establishing intellectual heritage and sources of influence as well as the evolution of particular ideas in various institutional, geographic, or sociopolitical contexts. Another approach to historical inquiry takes a close look at a particular individual, program, or organization, in ways similar to case study research. This type of historical inquiry can be presented alone with a great number of historical details or episodes. Those descriptions can also be compiled into a series of descriptions about major people, entities, and events in order to establish a chronology of events and to document the origin and development of ideas and practices as well as their interrelationships (Howatt, 2004). Yet another approach is to construct narratives about the development of applied linguistics, its subfields, or particular organizations or programs by weaving together various historical facts, making assertions about their relationships or the consequences of certain developments (e.g., Matsuda, 2001). *Revisionary* or *critical historiography* seeks to problematize dominant historical narratives by examining and rewriting the narratives, whether by identifying gaps and contradictions in the historical narrative (e.g., Musumeci, 1997; Matsuda, 2006) or by focusing on historically marginalized populations and perspectives (e.g., Matsuda, 1999).

In reality, these approaches are not mutually exclusive. The boundaries between different approaches are not static, and a single historical study may combine multiple approaches. All of them, including revisionary and critical historiography, participate in the construction of historical narratives, the process that imposes certain ways of understanding and organizing historical reality (Casanave, 2005).

Challenges to Historical Knowledge

One of the major challenges facing historians of applied linguistics is that there are so few of them. While some examples of serious historical scholarship do exist within the field of applied linguistics, they are still few and far between. Few graduate programs seem to offer coursework on the history of applied linguistics, beyond a brief discussion at the beginning of an introductory course. Historiography is also not widely discussed in publications, even in books on research methodology (for a notable exception, see Matsuda & Silva, 2005). In order for productive communal dialectic to take place, more applied linguists need to become aware of the nature of historical knowledge, how historical knowledge is constructed and negotiated, and how it influences the way we imagine our discipline—its past, present, and future.

History of Forensic Linguistics

SUSAN BLACKWELL

Forensic linguistics (FL) is a relatively young discipline compared with other branches of applied linguistics. The earliest attested usage of the term “forensic linguistics” dates from 1968, with the publication of Jan Svartvik’s analysis of four statements purportedly made to the police by Timothy Evans in which he confessed to strangling his wife and baby daughter in 1949. While in the second half of the 20th century a number of linguists produced reports of this kind for courts or about legal cases in various countries (see, for instance, Shuy, 1982a, 1982b; Eades, 1988; Butters, 1990), they could not be described as sharing an academic discipline, let alone a methodology: as Malcolm Coulthard puts it, “the work was usually undertaken as an intellectual challenge and almost always required the creation, rather than simply the application, of a method of analysis” (Coulthard, 1995, p. 1).

This situation was to change rapidly in the early 1990s, when a series of seminars took place culminating in the establishment of the International Association of Forensic Linguists (IAFL), the International Association for Forensic Phonetics (IAFP), and the journal *Forensic Linguistics: The International Journal of Speech, Language and the Law*.

The earliest gatherings of forensic linguists appear to have taken place in Germany: in 1988 the Bundeskriminalamt (BKA, Federal Criminal Police Office) in Wiesbaden organized a two-day conference in FL, while 1989 saw a number of conferences at Mannheim University organized by the late Lothar Michel. These latter were primarily concerned with forensic handwriting analysis but also accommodated presentations on other aspects of FL. From 1990 to 1992 the German Applied Linguistics Association (GAL) had a session (*Arbeitskreis*) on forensic linguistics in its program each year (in Göttingen, Mainz, and Saarbrücken respectively).

The Bundeskriminalamt can also be credited with pioneering the phonetic-acoustic tradition of forensic speaker identification, which is now practiced in government forensic laboratories in a number of EU countries including Germany, Austria, Sweden, the Netherlands, and Spain (Broeders, 2001). Meanwhile, in the UK Peter French organized conferences in York on forensic phonetics and linguistics, leading to the establishment of the IAFP in 1991.

The 1st British Seminar on Forensic Linguistics took place at the University of Birmingham on March 20–22, 1992, on the initiative of Malcolm Coulthard, and was attended by participants—mostly academic linguists and lawyers—from Australia, Brazil, Germany, Greece, Ireland, the Netherlands, and Ukraine as well as the UK. There was a consensus that an international association was needed, and it was from this gathering that the IAFL was born. The 2nd British Seminar on Forensic Linguistics followed within months, on November 14, 1992.

Following the founding of the IAFL, the discipline became visible on the academic conference circuit: the first IAFL Conference took place in Bonn, Germany on July 14–16, 1993, and a Special Symposium at the AILA (International Association of Applied Linguistics) Conference, Amsterdam was held on August 13 the same year, chaired by Professor Hannes Kniffka. Since then, the IAFL has convened conferences every two years, in various countries: a full list of these can be found on the IAFL Web site. The 1995 and 1997 conferences

were held in Australia and the USA respectively, indicating that the discipline had become truly international and that linguists in these countries, who had been testifying in court and publishing in academic journals for some years, had now become part of an international network which was helping to shape the discipline. The 4th IAFL Conference in 1999 proved to be larger than any of its predecessors, with over 80 participants from 13 different countries in four continents. Approximately 30 solo papers were presented, plus two symposia, a plenary lecture, and a software demonstration. For the first time in IAFL history it was necessary to organize parallel sessions. It is fair comment, though, that the participants still came predominantly from the English-speaking world and from common law legal systems modeled on the English one, with its adversarial rather than investigative courtroom ethos and the consequent polarization of expert witnesses into the "prosecution" and "defense" camps. Many academics feel uncomfortable in such a culture and would prefer to be called as experts for the court rather than for one of the opposing sides. Those who have served as expert witnesses for the court in a "civil law" system, on the other hand, have been heard to express the sentiment that the less confrontational culture of the Roman law model does not encourage rigorous thinking in the way that the cut-and-thrust of cross-examination does.

By the mid-1990s the discipline had come of age and the need for a journal was felt. Accordingly *Forensic Linguistics: The International Journal of Speech, Language and the Law* (original title) was established in 1994, published by Routledge, to serve as the official organ of both the IAFP and the IAFL. Its editors expressed the hope that it would "play a pivotal role in further developing, refining and testing . . . methodologies, in disseminating the results of research and in making available experience from case studies" (French & Coulthard, 1994, p. viii). It was "intended to appeal to readers and contributors from a number of different sub-disciplines of linguistics, as well as to solicitors, barristers and judges who have little or no prior knowledge of the concepts and terminology connected with linguistic study" (p. viii).

Birmingham 1999 was the first in the IAFL conference series to have its own Web site, created by Jess Shapero. At the time this was a pioneering effort, enabling potential participants around the world to remain informed about changes to the program without having to rely on the postal system. A general IAFL Web site (now at www.iafl.org) was established at around the same time, which continues to provide resources for members including an online searchable bibliography of research in language and law.

Another resource facilitating communication between the widely dispersed academic community with interests in FL was the discussion list instigated by Sue Blackwell. This rapidly expanded from a collection of e-mail addresses in her personal mailbox in the mid-1990s to a formal list hosted from 1998 by Mailbase in Newcastle, and then from 2000 by JISCMail, the national academic mailing service for the UK; "forensic-linguistics" currently has some 500 subscribers and has acquired a reputation for lively and witty exchanges, with only occasional outbursts of acrimony requiring intervention by the list owner.

In 2001 the list became the forum for a heated debate about the likely background of the individual(s) who had sent letters containing anthrax to a number of public figures in the USA including senator Tom Daschle. The consensus that emerged was that, despite the misspelled "penacilin," nonstandard syntax such as "we have this anthrax" and "you die now," and the final exclamation "Allah is great," the sender was likely to be a non-Muslim native speaker of American English. This assessment appears to have been correct: in 2008 the FBI prepared to prosecute Bruce Edwards Ivins, a white Roman Catholic scientist working at the US government's biodefense laboratory in Fort Detrick, Maryland. He committed suicide before the trial could proceed, but on August 6, 2008 federal prosecutors declared him to be the sole culprit for the attacks which had claimed five lives. In February 2010 the FBI formally closed its investigation.

By the end of the century conferences such as “Law and Society” and the American Association for Applied Linguistics regularly included symposia on FL. In 2002 a Scientific Commission on Forensic Linguistics was established by AILA.

The provision of university courses in FL grew steadily. By the end of the 20th century, undergraduate and/or postgraduate taught modules were emerging at universities in the USA, England, Wales, Australia, China, Hong Kong, Finland, Germany, Japan, and South Africa, to name but some of the better known examples. All the same, the provision was rather ad hoc and tended to depend on the research interests and enthusiasm of individual academics. Many countries still had very little to offer students wanting to pursue formal study in FL. An attempt was made to fill this lacuna by providing a series of international summer schools in forensic linguistic analysis, initiated by Malcolm Coulthard. The first of these was held at Anglia Polytechnic University in 2000, followed by four similar events in Birmingham and one in Łódź, Poland.

Łódź also played host to the “Language and the Law: East Meets West” conference in September 2005. The biennial IAFL conferences were clearly no longer sufficient to meet the demand for the exchange of ideas in the field, particularly for those academics in European countries whose resources did not permit travel to the USA or Australia. The Łódź event in 2005 was followed by the 2nd IAFL European Conference on Forensic Linguistics/Language and the Law in Barcelona in 2006, and by annual conferences at Adam Mickiewicz University, Poznań from 2006. The fact that academics from countries like Spain and Poland were now taking a lead in organizing conferences signaled a welcome shift away from the Anglo-centric, common-law bias which had tended to dominate the field in the first decade of the discipline’s active life.

The IAFL biennial conferences have nonetheless remained an important focal point for the discipline, not least because they provide the locus for the IAFL’s organizational meetings and election of officers. The IAFL has also occasionally felt the need to pass resolutions taking a position on current political issues of concern to its members. Most famously, at the Business Meeting held at the Sydney conference in July 2003 the Association unanimously carried a resolution proposed by Diana Eades condemning the Australian government’s use of so-called language tests in determining the national origins of asylum-seekers. Citing research by Dr. Eades and her colleagues (Eades, Fraser, Siegel, McNamara, & Baker, 2003), the motion condemned the tests as “unprofessional and unreliable” in both their assumptions and their methods, and called on the Australian government to desist from using the process until its reliability had been independently established.

Since its beginnings in 1994 the FL journal has undergone changes of both name and publisher: it is currently published by Equinox and entitled, since 2003, *The International Journal of Speech, Language and the Law*. The change in title of the journal reflects an emerging debate—perhaps even a tension—within the FL community concerning the scope of the discipline. The initial use of the term indicated, as Svartvik’s paper had done, the application of grammatical, lexical, and textual analysis to disputed documents, often for the purpose of giving expert evidence in court regarding authorship. However, from the earliest conferences of the IAFL other strands were apparent: lawyers discussed conflicting interpretations of terms used in court and linguists expressed concern over the frequent miscommunication between police officers and speakers of nonstandard language varieties, while courtroom interpreters presented papers examining the “linguistic human rights” of defendants and the often deficient quality of the interpreting services available to them. While in the early days papers on forensic phonetics (acoustic voice analysis, speaker identification from recordings) were commonly included in IAFL conferences, such work is now felt to belong to the territory of the International Association for Forensic Phonetics and Acoustics (IAFPA), which predates the IAFL and holds its own annual conferences (<http://www.iafpa.net/conf.htm>). The change in the journal’s title reflects, on the one hand,

the need to mark explicitly the inclusion of forensic speech analysis as a distinct discipline, and on the other hand the expansion of the nonphonetic aspects of FL to take in a wide range of areas of overlap between language and law, no longer restricted to expert evidence in legal or quasi-legal settings.

"Forensic linguistics," then, rather like the term "applied linguistics," has come to have both a broad and a narrow definition. The narrow meaning denotes the application of linguistic methods to the production of expert evidence, concerning for example disputed confessions (Coulthard, 1994), trademark disputes (Okawara, 2006), threats and attempts at extortion (Shuy, 1993), taped conversations in which individuals allegedly offer bribes (Shuy, 2005), suicide notes (Shapero, 2011), and disputed authorship and alleged plagiarism (Kniffka, 2000). The broader meaning—better labeled "language and law"—extends to the study of courtroom discourse (Solan, 1993; Tiersma, 1999), legal interpreting and translating (Berk-Seligson, 1990), the readability/comprehensibility of legal documents and jury instructions (Tiersma & Curtis, 2008), the comprehensibility of the police caution ("Miranda warning" in the USA) issued to suspects (Cotterill, 2000), linguistic minorities in the legal process (Eades, 1994), children in the legal process (Walker, 1999), and numerous other areas where language and law interact with each other. Judith Levi (1994) offered one early overview of the literature in all these areas and more, which was so comprehensive that it is still regarded as an invaluable guide to the field.

One of the long-standing aims of the IAFL has been to educate the legal profession about the role of linguists and the scope of linguistic evidence. While forensic linguistics inevitably overlaps with fields such as psycholinguistics and sociolinguistics, and its practitioners often deal with the same documents as colleagues working in ESDA (Electro-Static Detection Apparatus) or handwriting analysis, they will take pains to emphasize that they cannot give a professional opinion on whether or not a witness is lying, or could have written their statement unaided by the police. Conversely, the input of lawyers and judges has proved invaluable in enlightening linguists as to how they are viewed by the legal profession and how they are expected to frame their expert evidence. The Daubert ruling of 1993 in the USA was a watershed for expert witnesses working within the common law system, and it is largely thanks to the work of academic lawyers with an interest in language, such as Larry Solan and Peter Tiersma, that linguists have understood the necessity of being shown to engage with the standards of testability, peer review, acceptability, and known error rate (Solan & Tiersma, 2004).

The English legal system also appeared to be formalizing its standard for expert witnesses when, against a background of several high-profile convictions being overturned with the discrediting of the "experts" who had given evidence, an Independent Forensic Science Regulator was appointed in February 2008 and the Council for the Registration of Forensic Practitioners received some £2.9 million in grant aid with the requirement to be self-financing by March 2010. This has not occurred, however: according to a written answer in the House of Commons by the Home Secretary, this was largely due to the withdrawal of support by the police, which removed 70% of the Council's income (Hansard, HC Deb, May 11, 2009, c522W). The Council duly closed in 2009: it is not clear what organization will succeed it and what effect this will have on expert witness testimony by linguists.

Notwithstanding the lack of a framework for expert witnesses in many countries, cases of expert linguistic evidence in court have been many and varied, ranging from trademark violations, extortion, and plagiarism to aboriginal rights, terrorist bombings, and pedophile murders. Many of the early cases concerned appeals against convictions which had taken place years or even decades earlier. Probably the most extreme example of this was the posthumous pardon of Derek Bentley, whose guilty verdict was overturned in 1998 after 46 years, partly as a result of Malcolm Coulthard's report showing that the allegedly

"verbatim" record of Bentley's confession was no such thing. (By then, Bentley's notoriously ambiguous utterance "Let him have it," after which his accomplice Chris Craig shot and killed a police officer, had become the title of a 1991 film telling the story of this miscarriage of justice.)

The first case in an English court where linguistic evidence formed the sole or main grounds for allowing the appeal to be heard was probably that of *R. v. Daniel Raphaie* in 1996 in the Court of Appeal, Criminal Division (EWCA Crim 299). In cases such as this, the "youth" of forensic linguistics as an academic discipline was a crucial factor, since in the English legal system appeals cannot be based on evidence which was, or could have been, heard at the original trial. The court accepted that it would not have been possible for linguistic evidence concerning the contemporaneity of the police record to have been considered at Mr. Raphaie's original trial in 1989, since methods of forensic linguistic analysis had yet to be developed at that time. (In the event the appeal was allowed on legal grounds and Sue Blackwell's linguistic evidence was not heard.)

Linguists may of course give evidence for the prosecution as well as for the defense or the appellant. Perhaps the most famous instance in a US criminal case is that of the "Unabomber," so called because the principal targets of his mail-bomb attacks were universities and airlines. Following the publication in newspapers of the Unabomber's "manifesto" in 1995, a certain Ted Kaczynski contacted the FBI claiming to have recognized his brother Theodore's writing style, including the expression "you can't eat your cake and have it too," which although less common than "you can't have your cake and eat it" turned out to be an attested older variant. FBI special agent James Fitzgerald consequently conducted an analysis comparing Theodore Kaczynski's language with that of the Unabomber's manifesto: this was sufficient to persuade a judge to issue a search warrant for Kaczynski's cabin in Montana, the results of which led to his conviction and life imprisonment.

In recent years there have been a number of cases involving the analysis of the language of text messages sent from mobile phones. Typically the messages have been sent after the owner of the phone has disappeared, and the allegation is that the person responsible for abducting and murdering them has sent messages from their phone to allay suspicion and delay the hunt for the missing person. One particularly striking example was the conviction in February 2008 of David Hodgson for the murder of Jenny Nicholl, despite Hodgson's denials and the fact that her body had not been found since her disappearance almost three years earlier. The jury was persuaded by linguistic analysis showing that text messages sent from her mobile phone were unlikely to have been written by her but were closer to the style of Hodgson, her former lover.

A similar case is that of the trial of Peter Chapman in March 2010 for the murder of teenager Ashleigh Hall, whom he had befriended through the Facebook social networking site before arranging to meet her. The language of text messages sent from both his and Ashleigh's mobile phones was analyzed by John Olsson and contributed to Chapman's conviction.

While there is still no single accepted methodology in FL, the use of computer-readable language corpora is becoming increasingly common. General corpora such as the Bank of English are used for comparison purposes, and corpus tools such as concordances and collocation software are used to extract potentially significant patterns. There remains a need for specialized corpora of language in legal contexts (Blackwell, 2009), although collections of text messages are beginning to grow and have been used in the studies mentioned above.

May 13, 2008 saw the launch of the Centre for Forensic Linguistics at Aston University, which has hosted the FL Summer School, now an annual event, since 2006 and where Malcolm Coulthard now holds the world's first professorial chair in forensic linguistics.

The Centre now also runs a distance-learning master's program in FL. Master's courses are also currently being taught at the Universities of Bangor, Barcelona, Cardiff, Hofstra, and Pompeu Fabra (where the University's ForensicLab was officially opened in 2010), training what might be termed the "third generation" of students of language and law. Such developments, along with the growing acceptance of linguistic evidence in the courts of many countries, may well indicate that, two decades since the first seminars took place, the discipline has now achieved "critical mass" and will continue to extend its reach into the territory of both law and linguistics.

History of Interpreting

DÖRTE ANDRES

In the Bible, Prov. 18:21 reads “[D]eath and life are in the power of the tongue.” These ancient words convey the fact that language is a powerful tool, upon which life and death (may) depend. Solomon was certainly not referring to interpreters but, nevertheless, interpreters work with language, and they can use words to exercise power. There are many accounts of the power of interpreters. Some of these show that the question of life or death often depended on the interpreter. Other accounts illustrate the responsibility invested in interpreters and how the right or false handling of that responsibility determined the fate of individuals and even peoples. What do we know about interpreters in history? What were their tasks? Locating historical accounts of interpreters is arduous, since accounts are few and far between and most interpreters are only mentioned in passing (Hermann, 1956; Roland, 1982; Bowen, Bowen, Kaufmann, & Kurz, 1995; Wilss, 1999; Pöchhacker, 2000; Wiotte-Franz, 2001; Andres, 2008). Although more information is now available concerning the “Eastern world” (Kaufmann, 2005; Lung & Li, 2005; Lung, 2006), most accounts refer to the “Western world,” which is thus the focus of this entry.

Evidence can be found about the work of interpreters going back to the age of the pyramids. Interpreters were working for the state, the church, the military, for adventurers, conquerors, and diplomats. They were often needed but rarely mentioned:

interpreters have been largely ignored by historians for two reasons. First, there is often a total lack of historical documentation. People of power and influence in centuries past seldom considered a mere interpreter’s name to be worth recording. Secondly, most historians, confined to “important” events and to the limitations imposed by the desired size of their books, cannot be expected to include every intriguing tidbit they may uncover. (Roland, 1982, p. vi)

Interpreters’ multilingualism often gave rise to suspicion, as the interpretation was hard to control and nobody really knew what the person being interpreted was actually saying. The suspicion was often justified because most early interpreters were prisoners or slaves. Conquerors brought the conquered to their native country in order to teach them the language of the conquerors and to use these prisoners as interpreters in subsequent conquests. The common understanding was that the mere knowledge of two languages sufficed to make a person an interpreter. It soon became apparent, however, that the knowledge of two or more languages alone did not bring the desired outcome, as the loyalty of the interpreter in question was essential for successful communication.

Interpreters in Ancient Egypt

The oldest available sources about interpreters date back to ancient Egypt, where interpreters worked at the pharaoh’s court. By the third millennium BC, the Egyptians had already abandoned nomadism, and the settlements and realms which had developed were unified under King Menes in 2920 BC. From the city of Memphis he tried to protect his kingdom against the surrounding peoples. The kingdom was divided into districts, which

DOI: 10.1002/9781405198431.wbeal0509

were governed by nomarchs. Thus, a huge administrative system soon encompassed all of Egypt. At the time, all foreign peoples—Nubians, Libyans, and Asians—were considered to be “barbarians” and not equal partners. In order to communicate with these “barbarians,” the court employed interpreters, just as for trade with foreign countries and for military expeditions. Inscriptions on the walls of the tombs of the princes of Elephantine, in the Egyptian border region with Nubia, date back to about 2600 BC. In this region the Egyptian and Nubian peoples mingled and the inscriptions show that the nomarchs were often bilingual and often half Nubian. They were diplomats responsible for economic, military, and political affairs at the pharaoh’s court, bearing the title of “overseers of dragomans” as mentioned in the inscriptions in the tombs. The relief found in the tomb of Haremhab also depicts these facts (Aegyptologie, *n.d.*, Scene 76-1f). The relief depicts an audience with the pharaoh Tutanchamun. Vassals (probably) from Syria and Libya lie at his feet and ask him for food and shelter from invading enemies. Haremhab, who was a prince before he became pharaoh, is located between the two parties. He is depicted as a double figure situated slightly below the pharaoh. The left figure informs the pharaoh of the problems of the vassals while the right figure passes on the pharaoh’s words to the actual interpreter. This interpreter is also depicted as a double-figure, symbolizing his role as intermediary. Slightly bowing, the left figure of the interpreter stands at Haremhab’s feet, looking up to him and listening devoutly to the words of the nomarch. The right figure passes on the response of the pharaoh to the vassals, standing on equal footing with them. The depiction leads to the conclusion that interpreters were not regarded very highly. Their social status was probably equal to that of merchants and seamen, as can be deduced from the hessian loincloth worn by them, which alludes to the mute trade between the primitive peoples who printed the price of their goods on these cloths. Accordingly, interpreters were individuals of fairly low rank and were not much respected (Gardiner, 1953; Hermann, 1956; Thieme, 1956; Kurz, 1985, 1986).

Interpreting in Ancient Greece and the Roman Empire

In antiquity, interpreting was an important profession which was exercised by many individuals in diplomacy, in the military, and in administration. Interpreting was considered to be a profession in its own right and interpreters greatly facilitated communication between the different peoples (Wiotte-Franz, 2001). There is proof of interpreters’ existence: Wiotte-Franz (2001) has compiled a catalogue of interpreters in antiquity, 61 of whom are listed by name, 112 anonymously. This valuable publication includes ample detail with regard to the interpreters’ activities, their spheres of influence, and even their achievements.

Interpreters also played an important role in the area of philosophy. Alexander the Great gave the Greek historian Onesikritos the assignment to conduct research into the philosophical teachings of the Indian ascetics (Wiotte-Franz, 2001, p. 149). A discussion took place between Onesikritos and Dandamis, the oldest of the Indian wise men. Three interpreters were present during the discussion and, since there was apparently no Greek–Indian interpreter available, the first interpreter probably interpreted Dandamis’s words into an Iranian dialect, after which the second interpreter translated them into Aramaic. The third interpreter then conveyed the words from Aramaic into Greek (Franke, 1992, p. 93). Communication problems arise as the three interpreters do not grasp the meaning of what is said, rendering them unable to convey the opinions of Onesikritos, who subsequently announces that communication through interpreters was like pure water flowing through swamplands (Strabo, 1961, 15.1.64).

Like the Egyptians, the Greeks also considered their language the only one worthy of human usage. They also regarded foreigners as “barbarians” and were generally unwilling

to learn new languages. Interpreters in those days often had bilingual parents or they were “barbarian children” who learned Greek as slaves in Athens (Wiotte-Franz, 2001).

In contrast to the Greeks, the Romans were often bilingual, and an educated Roman was expected to speak two languages. Greek and Latin were taught in schools and the two languages were considered equal. Young Romans studied abroad in Greece. In the Roman Empire, interpreters were used not only in order to overcome language barriers but also to satisfy national pride, to distance oneself from foreigners, thus increasing one’s own prestige (Gehman, 1914, p. 56). The Roman Senate was one of the main administrative bodies which regularly employed interpreters, as Carthaginians and Hispanics were only allowed to speak with interpreters (Cicero, 1923, II, p. 131). The same held true for the Roman courts. Interpreters thus belonged to the “apparitores”—those in steady employ of the administrative system. By means of the Latin language and interpreters, the Roman Empire demonstrated its military and political power (Cassio Dio, 1844, pp. 78,6,2).

Accounts from the era of the Roman Emperor Caracalla illustrate how dangerous an interpreter’s work could be. Since interpreters were considered potential betrayers of secrets, Caracalla executed all interpreters who were present during secret negotiations right after the conclusion of such talks in order to rule out any risk of betrayal, as the interpreters were the only witnesses to what had been said (Cassio Dio, 1844, pp. 78,6,2).

There are records about the work of interpreters in the context of peace negotiations. Prokop reports that the Persian envoy Isdigusnas was sent to Constantinople by the Persian ruler Chosroes I to negotiate with the Romans in AD 548 (Wiotte-Franz, 2001, pp. 131–2). He was accompanied by his interpreter Bradukios. The envoy and his party stayed in Constantinople for 10 months after having been received with hospitality and great honors, which were mainly bestowed upon the interpreter, who was allowed to dine at the emperor’s table. Prokop’s account indicates that interpreters were of low social standing and would usually be expected to stand behind the emperor to interpret during meals. The honor granted to Bradukios, however, led to his ultimate demise. Chosroes—who suspected that the honor of dining with the emperor had only been bestowed upon the interpreter because he had earned it by betraying Roman interests or by having conducted secret negotiations with the Romans—ordered Bradukios to be executed upon his return to Persia.

Interpreters in the Middle Ages

There are a range of written records on interpreters, albeit fragmented, stemming from Christian late antiquity and the Roman Empire. Written culture as a whole declined with the onset of the migration period, so that information on interpreters is particularly sparse until the eighth century. It is not until the high and late Middle Ages that interpreters once again begin to emerge.

French medieval heroic epics called *chansons de geste*, for instance, illustrate the distinct social standing of the interpreter in the Middle Ages. His title “maistre latimier” is proof of a certain renown and places him in a particular occupational class (Glässer, 1956, p. 70). Thus, Charlemagne asks for God’s blessing for an interpreter who had converted to Christianity and was especially devoted to him (Gächter, 1936).

Proselytization was a much more problematic context for interpreting. The beginning of the crusades, launched by the Western church at the end of the 11th century to free Jerusalem and the Holy Land from the rule of the “infidel” Muslims, saw interpreters increasingly being used in missionary work, with their performances minutely commented on. Louis IX sent Wilhelm von Rubruk to the Mongolians, since a rumor in the Western world claimed Khan Sartach had converted to Christianity. Rubruk had orders to investigate these rumors

4 HISTORY OF INTERPRETING

and initiate permanent missionary work among the Mongolians. Presumably, Louis also hoped for Sartach as an ally in his fight against the Saracens. Upon his return, Rubruk drafted an *Itinerarium* which included notes on his interpreter Homo Dei, in other words Abdullah (Bowen et al., 1995, p. 252). Homo Dei appears to have been of Muslim descent. He possessed neither the necessary language skills in Tartar nor the requisite understanding of the philosophy of religion to provide an adequate mediation. Whenever Rubruk wants to preach, his interpreter refuses his services:

“Do not make me preach, since I do not know how to express these things”. He was right. Later, when I acquired some little knowledge of the language, I noticed that when I said one thing he would say something totally different, depending on what came into his head. After that I realized the danger of speaking through him, and chose rather to say nothing. (Rubruk, 1990, p. 108)

During the exceedingly strenuous journey into the winter months, Rubruk’s fellow travelers and guides long for the comfort of God’s Word. However, Homo Dei is so incompetent that Rubruk realizes it would be dangerous, if not impossible, to have the doctrine translated by such an interpreter, notable not only for his ineptitude but also for his insobriety (Rubruk, 1990, p. 179).

Since interpreters are mentioned by name during the Middle Ages, their line of work was obviously in demand, well established, and widespread; however, it also becomes clear that it was of doubtful reputation, particularly in the religious realm (Atiya, 1970, p. 75).

Interpreters in the Modern World

An interest in religious expansion is only one of many motives behind expeditions to Africa and voyages from the Old to the New World. Other objectives are trade, power, and the conquering of new lands. Since not enough interpreters were available in the 16th century, interpreters were “obtained” according to contemporary customs, meaning that members of the indigenous population, for instance, were kidnapped and taught the language of the conquerors. It stands to reason that this method did little to endear the conquerors to the future interpreters. These often retaliated, either by escaping or by betraying their “employers” at the first opportunity. This method was followed by Columbus, too, who during his conquests sought to capture natives on the various islands so that they might later serve him as interpreters and guides. He hoped that taking the prisoners’ wives along to Spain would buy him the loyalty of the indigenous men. However, the prisoners’ numerous escape attempts made it clear to him that he could trust these interpreters only to a very limited extent (Kolumbus, 1981, pp. 128–30, November 1492; Dirksen, 2006, pp. 209–11).

Hernán Cortés, by contrast, had the services of two competent and loyal interpreters to rely on: the shipwrecked Geronimo de Aguilar and the indigenous slave Malinche (Lanyon, 2001). Aguilar had been shipwrecked near the Jamaican coast in 1511, whereupon he spent several years as a slave of the Maya, learning their language. Nevertheless, he never ceased to hope for rescue. His hopes were met when the expedition landed and Cortés took him on board. Aguilar proved exceedingly useful to the Spanish, for whom he interpreted during their talks with the Maya.

Malinche was a gift for Cortés, which he received at the beginning of his conquest in 1519. As a child, she was sold to the Maya. Díaz del Castillo (1968) relates how she fell victim to her own mother’s plotting: having remarried after the death of Malinche’s father,

her mother wanted to establish her son from the later marriage as sole heir. When Cortés landed on the coast, Malinche was a slave to the local Maya. She, too, quickly proved invaluable as a language facilitator for, as the Spanish advanced further into the heartlands toward Tenochtitlan, Geronimo de Aguilar suddenly ceased to understand the natives. They no longer spoke the Mayan language, but instead used Nahuatl, the language of the Mexica, which Malinche was familiar with. Her command of both the Mayan language, learned during her stay with the Maya, and of Nahuatl made her indispensable for Cortés. “Her job was remarkable for the Spaniards” (Araguás & Jalón, 2004, p. 135).

In 1517, the Spanish seafarer Francisco Hernández de Córdoba sailed on an expedition from Havana to Yucatán by order of the Spanish conquistador Diego Velásquez de Cuellar. The Spanish remained with the Mayan people for a few days but failed to understand their language. They therefore took two young Indians—who received the Christian names of Melchorejo and Julianillo (Díaz del Castillo, 1968, pp. 42–50)—back to Cuba, where they were to be trained as interpreters. Julianillo died there; Melchorejo learned Spanish and was taken along on the next expedition to Tabasco to act as interpreter. This, however, never bore fruit: Melchorejo escaped at the first opportunity and allied himself with the local Indians against the Spanish (Díaz del Castillo, 1968, p. 76).

During his second expedition to the west coast of South America, the Spanish explorer Francisco Pizarro took three Incas on board to be trained as interpreters. Two of these were Felipillo and Martinillo. In 1532 Pizarro returned to Peru, intending to exploit the state of civil war in order to conquer the country and gain control over the considerable gold deposits. Felipillo acted as his interpreter but proved to be totally incompetent (Roland, 1982, pp. 64–5; De la Vega, 1983, pp. 467, 479; Kurz, 1991, p. 3).

In French Canada Jacques Cartier—on his first voyage to Canada in 1534—captured two Iroquois and took them to France to train them as interpreters. On his second voyage in 1535, the two Indians were used to help him as interpreter-guides, but only did so as long as their own people’s interests did not oppose those of the French (Delisle & Woodsworth, 1995, p. 259).

The French explorer and founder of French Canada, Samuel de Champlain, was more successful. In 1608, he instituted the system of *interprètes-résidents* (Delisle, 1977, pp. 6–8; Bowen et al., 1995, p. 257). Young Frenchmen lived among the Canadian native tribes in order to learn their language and culture, gain their trust, and thus further the interests of the French conquerors (Dionne, 1963; Morison, 1972).

Interpreters played an active role in the Ottoman Empire as well as in the conquests of the New World. Since the government of the Ottoman Empire made it a principle never to converse with other powers in writing, communication was dependent on the so-called Levantine dragomans. Embassies in the capital, but also consulates in many provincial cities, relied heavily on them, since few of the foreign ambassadors/consuls spoke Turkish, and interpreters were needed for all talks and discussions with the Turkish side. However, the interpreters were accused of incompetence, mistranslation, and disloyalty, and of serving their own interest and selling their services to the highest bidder (Lewis, 1999). Mistranslation was frequently due to the fact that dragomans were too frightened to be able to interpret properly and to honestly transmit messages that the Turkish might take as an insult. This stemmed from fear of a violent Turkish reaction, since the Turkish historically did not subscribe to the Western principle that the bearer of bad news was not to be held responsible for the content of the message. It was not uncommon for interpreters to be abused verbally or physically, jailed, or even hanged or impaled simply for transmitting unpalatable messages to the sultan (Corbett, 1928, p. 122; Roland, 1982, p. 54), so all the embassies in Constantinople faced the problem of having to find competent, trustworthy, and brave interpreters. European powers consequently decided that the only solution was to train people of their own (Lewis, 1999).

Interpreters and Interpreting in the 20th Century

Until the end of World War I, a distinction was rarely made between interpreters and translators. It was assumed that a language expert could be called on for both. During the interwar period, the number of high-level contacts increased due to the development of large international organizations like the League of Nations (1919) and the International Labour Organization (ILO; 1919), and the need for interpretation into many languages multiplied: This marked the inception of what we know today as consecutive interpreting. During speeches, interpreters took notes in special shorthand that had been developed for this purpose, and interpreted what had been said afterwards.

The high quality of the League of Nations' interpreters has been stressed repeatedly; among them were Paul Mantoux (Jalón, 2004a, pp. 24–5) and André Kaminker (Ranshofen-Wertheimer, 1945, pp. 140–2). However, they are also known to have acted without authority. When a speaker complained to André Kaminker that the interpretation did not correspond to what he had said, the interpreter replied laconically: "No, sir, but it is what you ought to have said" (Longley, 1968, p. 4). It seems that this behavior was not held against him. The work of the League of Nations' interpreters was evidently worth being commented on in detail by historians. Consequently, interpreters were much more in the spotlight than ever before (Jalón, 2004a, pp. 53–5).

Since consecutive interpreting took up almost as much time as the original speech and hence prolonged meetings considerably, another form of interpreting was developed, which was to be less time-consuming: simultaneous interpreting (Jalón, 2004a, pp. 139–42). During simultaneous interpreting, the speaker speaks into a microphone which connects him/her directly with the interpreter, who in turn is connected to the listeners. Listeners can select the desired channel and thus the desired language. At first, interpreters fought bitterly against this technique. They feared they might not have the time to think about what they had heard or to find the most elegant expression.

This new interpreting technique was employed during the Nuremberg trials (1945–6), which were interpreted into English, French, Russian, and German. The interpreters sat in close proximity to the accused; the individual booths were only separated at the sides by glass panes. Three interpreters worked in each booth: The English booth for example contained one interpreter who interpreted from German into English, one who interpreted from French into English, and one who interpreted from Russian into English. The interpreters worked into their respective native tongue. There is a plethora of literature on how they perceived the trials (Gaiba, 1998; Sonnenfeldt, 2003; Stupnikova, 2003; Jalón, 2004a; Behr & Corpataux, 2006; Kalverkämper & Schippel, 2008; Ramler, 2008). The simultaneous interpretation not only made it possible to shorten the trials considerably, but also contributed to the popularization of the simultaneous technique, which was to some extent also used at the international military tribunal for the Far East (1946–8) in Tokyo (Kurz, 2004; Takeda, 2008; Torikai, 2009).

During the second half of the 20th century, simultaneous interpreting became more widely accepted and was subsequently used at the United Nations from 1947 (Jalón, 2004b), as well as at the EU for the interpretation of its 23 official languages. In 1953, the institutionalization of interpreter training and the growing professionalization of interpreters led to the foundation of the Association Internationale des Interprètes de Conférence (aiic), an international professional association of conference interpreters. Today, aiic has more than 2,800 members in more than 90 countries.

This was also the time when the first interpreter autobiographies were published, providing an insight into the work of interpreters in the 20th century (Dollmann, 1948, 1956, 1963; Schmidt, 1952; Ekvall, 1960; Jacob, 1962; Birse, 1967; Weit, 1970; Walters, 1990; Bereschkow, 1991; Kusterer, 1995; Palaschtschenko, 1997; Korchilov, 1999). More recent

harrowing insights into the work of interpreters in conflict or war zones are also available (Kahane, 2007, 2008), for example from Yugoslavia (Stahuljak, 1999; Suljagić, 2005; Dragovic-Drouet, 2007; Nuhanović, 2007), from Darfour (Hari, 2008), from Iraq (Goldfarb, 2005; Williams, 2006; Palmer, 2007; Guidère, 2008), or from international criminal courts like the ICTY (Stern, 2002; Hajdu, 2006; Seleskovitch, 2008) and from prisons like Guantánamo and Abu Ghraib (Saar & Novak, 2005; Willemsen, 2006; Khan, 2008).

Since the 1950s, interpreting has undergone an impressive development with regard to its diversity. New fields and types have been added, such as community interpreting and signed language interpreting, and new technologies and means of communication have been introduced. Media interpreting has increased, as well as video interpreting, telephone interpreting, and interpreting via the Internet. The tedious search for terminology in a dictionary has become outdated. Interpreters now compile glossaries for preparation on their computers, and using a computer in the booth has become the rule rather than the exception. Researchers are constantly developing new tools, like Personal Digital Assistants (PDAs), which are to some extent already being used for interpreting, for instance in the public health sector or in war zones; the Phraselator, which was used in Afghanistan (Afghanistan, 2002); the Multilingual Automatic Speech-to-Speech Translator (Mastor) (IBM, 2006), for soldiers in Iraq; or PDA-Phones (PDA-Phones, 2005), which were used in Munich during the FIFA World Cup.

In today's globalized world, translation has gained new relevance. Interpreters are more indispensable than ever in a global society, since communication is a fragile commodity in a multiethnic and multilingual environment. In the interest of all and in order to minimize conflict, it is to be preserved: "Translation it is that openeth the window to let in the light" (Bible, preface to the King James Version).

History of Language Teaching Methods

SUZANNE K. HILGENDORF

Language teaching methods refers to the set of teaching practices, approaches, and materials used by instructors to facilitate foreign-language (FL) learning. Throughout history, methods have responded to the changing goals of language learning, for example, communicating with foreign trade partners, supporting missionary efforts to spread religion, reading academic scholarship and sacred texts, or, most recently, facilitating interaction on transnational and global levels. Language teaching methods therefore have prioritized different skills, for example, listening comprehension, speaking, reading, and writing, given the needs of learners and the values of societies. Various theoretical understandings of second language acquisition (SLA) and FL pedagogy have further informed teaching methods. In particular, new research developments, emphases, and trends in the related disciplines of linguistics, literature studies, education, and psychology have shaped thinking on the most effective ways to teach FLs.

Undoubtedly a rich array of teaching traditions exists throughout the world. Due to space limitations, this account is restricted to methods developed in Europe and North America. The entry initially outlines historical factors that shaped the first formal teaching methods. It then describes the numerous methods developed since the 19th century.

Early History

In Europe, written records concerning FL teaching first appear in the fifth century AD (Musumeci, 2009, p. 43). Rather than discussing language teaching in general, these writings largely address the instruction of Latin, which had been the official language of the Roman Republic (509 BC to 27 BC) and Roman Empire (27 BC to AD 476). With a singular status as the primary FL throughout much of Western and Central Europe as well as the Mediterranean region, Latin functioned as “the universal language of scholarship, education, government, and the marketplace” (Musumeci, 1997, p. 4). A second language widely taught during this period was Greek, due to the influential achievements of classical Greece (ca. fifth and fourth centuries BC) in politics, philosophy, the arts, sciences, and literature.

Following the fall of Rome, Latin maintained its standing as primary language of wider communication for centuries, even though it was eventually no longer spoken as a native language (L1) and evolved into the distinct regional varieties of the present-day Romance languages and dialects. Thus for more than 1,000 years FL teaching was primarily understood with reference to Latin and to a lesser extent Greek, the classical languages in which most academic, literary, and sacred texts had been written (Musumeci, 2009, p. 43).

The Grammar-Translation Method

By the end of the Middle Ages, language study gained broader significance as universities were established throughout Europe and the *Studia humanitatis*, or studies in the humanities, grew in popularity. The dominant teaching method during this period was grammar-translation (G-T), which had evolved out of the historical focus on learned writings in

2 HISTORY OF LANGUAGE TEACHING METHODS

Latin and Greek. As its name suggests, G-T emphasized a thorough understanding of the target language (TL) grammar along with extensive exercises in translating texts between the TL and the learner's L1. Learning involved studying vocabulary lists and memorizing grammatical paradigms illustrating the various forms, for example, of verbs. Teaching activities included lectures with deductive, or explicit, grammar presentations, the recitation of memorized passages, and dictation exercises, all of which were facilitated by discussion in the L1. The TL was regarded as an object of study, with instruction also providing learners greater understanding of their L1 (Musumeci, 2009, p. 52; Rodgers, 2009, p. 345).

With instruction dealing primarily with Latin, G-T was oriented to the grammatical characteristics of that language. Grammatical terms were coined in Latin, and teaching focused on the language's extensive case system (Neuner, 1995, p. 182).

The Direct Method

Vernacularization in Europe beginning in the 15th century, which saw the increasing use of local languages in domains traditionally reserved for Latin, brought a broader understanding of FL study. By the late 19th century, the exclusive focus on classical languages expanded to include the contemporary modern languages of Europe, and the fact that, for example, French, German, and English had large L1 speech communities increased the importance of oral skills.

As a result, the direct method (DM) was developed, modeled on beliefs about L1 acquisition. Based on the fact that children hear a significant amount of language before producing speech, DM prioritized initially teaching listening comprehension through immersion, that is, the exclusive use of the TL in instruction. Teaching consequently first focused on the tangible environment and concrete objects. Speaking skills next were taught through direct language use, preferably by having learners perform the physical actions of what was said (Omaggio, 1986, p. 57). Various linguists contributed aspects to this method, which often were counter to established G-T practices. In 1874, Lambert Sauveur advocated for inductive grammar teaching, requiring learners to discover rules on their own based on the language input received, and in the late 19th century the US language school founder Maximilian Berlitz introduced an emphasis on conversational language use. Earlier, in 1866, Gottlieb Heness had introduced the natural method, a variant more closely replicating L1 acquisition (Adamson, 2004, p. 607; Neuner, 2007, p. 228).

Audio-Lingual Method

Developments in the fields of linguistics and learner psychology in the first half of the 20th century brought new impulses to language teaching. Ferdinand de Saussure's research conceptualizing language as a formal, static system introduced a structural approach to language study. In North America, linguistic interest in documenting Native American languages cultivated a disciplinary emphasis on spoken language, while in learner psychology the behaviorist framework, developed chiefly by B. F. Skinner, viewed learning as a conditioning process based on stimulus and response. Language learning was seen as an issue of habit formation, with speech being a response to linguistic stimuli (Omaggio, 1986, pp. 22–6; Neuner, 1995, pp. 183–4).

The audio-lingual method was developed in the 1940s and 1950s, emphasizing the study of recurring patterns in language, especially the phonological (sound) and morphological (word construction) systems, and the development of oral skills. As in L1 acquisition, language learning was believed to have a natural order, progressing from listening comprehension and speaking to reading and writing. Still incorporating inductive approaches

to grammar, instruction focused on memorized dialogues and pattern drills, as it was believed acquisition was facilitated by repetition, restating information, and practicing verb and noun forms (Omaggio, 1986, pp. 60–2; Rodgers, 2009, p. 346).

Cognitive Approaches to Language Teaching

Noam Chomsky's linguistic research on the cognitive dimensions of language acquisition significantly challenged the tenets of behaviorism and ALM. In Chomsky's (1959, pp. 56–8) critical review of Skinner's *Verbal Behavior* (1957), among his strongest arguments was the observation that L1 speakers interpret novel utterances, that is, sentences they have never heard before; therefore language acquisition cannot simply be an issue of mimicry as exemplified in ALM dialogue memorization exercises. Rather than relying on an inventory of linguistic stimuli and conditioned responses, language acquisition must involve rule-governed, deep processing in the brain.

Chomsky's scholarship led to a modernization of DM. One particularly influential cognitive theory for FL pedagogy was Stephen Krashen's (1982) monitor model. His five hypotheses included (a) a distinction between (subconscious) language acquisition and (conscious) language learning; (b) the recognition of a natural order for the acquisition of grammatical form, which is impervious to the sequence in which form is taught; and (c) the need for comprehensible input ($i + 1$). Krashen's model inspired many popular new methods, including Tracy D. Terrell's (1982) highly influential variation of the natural approach prioritizing the teaching of communication skills over grammatical form (Omaggio, 1986, p. 75).

Communicative Language Teaching

Since the 1970s, there has been "widespread acceptance . . . of communicative competence as the goal of [foreign] language learning" (Mitchell and Myles, 2004, p. 3). The recognition of communication as an interpersonal/social behavior, as a "continuous process of expression, interpretation, and negotiation of meaning," has influenced language teaching to incorporate such aspects into the learning experience (Savignon, 1997, p. 14).

The sociolinguistic conceptualization of communicative competence comprises several component competencies. In addition to grammatical competence, there is sociolinguistic competence: appropriate language use within a particular context of situation; discourse competence: language use beyond the sentence level; and strategic competence: mastery of communication tactics, that is, paraphrasing, circumlocution, guessing, and so forth (Canale and Swain, 1980; Savignon, 1997, pp. 40–4).

As outlined by Lee and VanPatten (2003), one major distinction of communicative language teaching (CLT) is the role of the instructor, which shifts from that of the transmitter of knowledge (Atlas complex) to being a resource person/architect responsible for creating student-centered learning activities that facilitate the exchange of information and negotiation of meaning. With students working primarily in pairs and groups, teaching further addresses learning strategies and individual learner styles.

Conclusion

Although FL teaching methods have evolved over centuries based on learner goals and advances in research, in practice instructors continue to draw on approaches from the past, which is a testament to the historical significance of G-T, DM, and ALM. This occurs in

4 HISTORY OF LANGUAGE TEACHING METHODS

spite of extensive training in CLT, most likely because of the challenging nature of reconceptualizing one's understanding of both SLA and the methods for facilitating that process. Instructors inevitably are most intimately familiar with the methods they experienced firsthand as language learners themselves, and these have been perpetuated over generations. They are so pervasive that even teachers who believe they employ CLT in actuality may use, for example, ALM exercises, such as when having students do partner activities that in fact only require them to repeat "correct" responses to provided queries, as opposed to having them truly communicate by exchanging information and negotiating meaning. These realities speak all the more to the importance of raising awareness of the rich history of language teaching methods.

History of Multilingualism

RITA FRANCESCHINI

Multilingualism is a human potentiality which can be developed when circumstances permit it anywhere and at any time throughout human evolution: Sporadic or prolonged language contact between populations through cohabitation, trade, intermarriage, conquest, exploration, travel, or shared interests raises the desire or need for exchange. These direct contact situations heighten the probability that speakers and entire groups become able to understand, speak, or write several languages, to a greater or lesser degree (functional multilingualism).

Multilingualism can also develop through mediated means, like an interest in studying written texts, through administrative acts or religious practices expressed in languages other than the commonly used one, or through teachers. All these contribute to form a dynamic landscape of language diversity with regional, historical, cultural, and ideological differences. Broadly speaking, what multilingualism means is the use of more than one language socially, or in everyday life by individuals or groups or in institutions (Franceschini, 2009, pp. 33–4).

The interest in exploring all these facets of multilingualism with historical depth is still in its infancy. The state of the art is built on case studies mainly from cultures with widely available written documentation; unfortunately, these are not necessarily the regions with the highest language diversity (today these include Papua New Guinea, Indonesia, Nigeria, and India; see Nichols, 1992), where colonial languages were often imposed as well (mainly English, Spanish, and French).

The traces or reports of the different phenomena of bilingual speech or writing—such as code switching, code mixing, code alternation, and accommodation to speakers of other languages—bilingual annotation of texts (in glosses for example), and different types of mediation and translation can be found in written documentation. Since an individual does not usually master different languages to the same degree, we can deduce that, in the past, some individuals' languages were used and understood in a limited way or only for specific purposes (for reading or for ritual purposes, for example). Thus, receptive multilingualism (which is not passive at all) can be practiced when each person understands another language to some extent and needs not acquire a perfect command of it (Braunmüller, 2007).

Entire languages like pidgins or lingua francas—also sign languages—emerged from the need for intercultural communication and for specific functions (mainly for trade) (Wurm, Mühlhäusler, & Tryon, 1996): One of the most durable lingua francas was used in the Mediterranean from the 13th to the 19th century for trade, naval communication, communication with foreigners, and other practical situations. This Mediterranean lingua franca (which also gave this phenomenon its name) was a sort of grammatically simplified mixed language based on several Italian vernaculars (Venetian, Genoese) with a fluxing addition of French forms and other languages from the Mediterranean basin, thus being comprehensible to people with different linguistic backgrounds.

Languages can come under pressure: A language can fade out of the repertoire of an individual or a group. This language shift can take place over generations, when a group moves to another linguistic environment or when the social circumstances and power relationships are negative to the maintenance of the original language(s): Conquests,

2 HISTORY OF MULTILINGUALISM

colonization, migration, and minority contexts may create the conditions for language loss and therefore contribute to diminishing multilingualism. The forced assimilation of Native Americans to English culture is one such case. People may, by contrast, be determined to maintain an inherited language against the pressure of others, signaling group solidarity through its use too (as in the maintenance of Basque to this day as a pre-Indo-European language or the case of Hebrew in the Jewish culture, maintained around the world through religious practices).

The most interesting topics in the history of multilingualism are how attitudes toward multilingualism have changed over time, and how ideology, mainly nationalism, has forced people toward monolingualism.

Sumerian and Ancient Egypt

One of the oldest sources documenting an administration's need to train people for multilingual purposes in a large empire goes back to the Sumerians: A huge number of multilingual vocabularies and grammars on clay tablets (ca. 2600 BC) impressively show that multilingually skilled persons, mainly civil servants, were deliberately trained to be able to speak and write in the different languages of the empire, such as Sumerian and Akkadian (Kramer, 1981, pp. 3–7; Titone, 1986, pp. 10–12, 25–6; van Hoof, 1991, pp. 7–8). Similar texts were also found from the Hittite Empire (till 1180 BC) (Macqueen 1986, pp. 24–5); and the same holds true for a multitude of ancient Egyptian sources (found in El-Amarna, for example, in 1400 BC).

Egypt preserves a long history of multilingual scriptural practices: From the arrival of the Greeks up to the ninth century AD one can trace bilingual texts for over a millennium. A large collection of papyri, for example, contains writings from various levels of society, private letters (written perhaps with help from scribes), and administrative documents in Demotic, Greek, Latin, Coptic, and Arabic (Papaconstantinou, 2010).

The Roman Empire (up to the Fourth Century AD)

From the early Republic on, Latin was in contact with a multitude of other languages spoken in the vast territory of the Roman Empire, for instance Oscan, Gaulish, Punic, Aramaic, and Greek. Adams (2003, p. xxi) argues that a substantial part of the population in contact with Romans, and the Romans themselves, must have been bi- and multilingual. Evidence is given through traces of code switching from inscriptions to literary texts (for example in the works of Plautius and Lucilius; Cicero's code switching in his personal letters is described in Swain, 2002).

Important institutions in the Roman Empire were multilingual: In the army, Latin and Greek were used, and the latter played an important role in the eastern part of the empire, where it assumed the role of a *lingua franca*. People with non-Latin languages as their L1 had to choose between learning Latin or Greek alongside maintaining their inherited language(s), or shifting completely to the language of authority, Latin, by giving up the language of their ancestors. In the west of the Roman Empire, a shift to Latin was the most common tendency, but in other countries communication through Greek formed a consistent pattern (Adams, 2003, p. 757).

Another important institution was slavery: Many slaves were Greek and also worked as teachers in upper-class families, in Rome for example. This fostered the learning of Greek as a prestigious language (Adams, 2003, p. 762).

The Roman Empire did not have an explicit language policy, imposing the learning of Latin, but the expectation—and the necessity—to learn Latin was pretty convincing:

For socially powerful interaction, submitted alloglott speakers had to come to grasps with the language of the dominators. A certain pragmatism combined with a dismissive attitude toward local languages (except Greek, which was admired) seems to have prevailed over an officially spelled-out policy. And, mainly in the west, a certain degree of disregard for regional languages like Etruscan and Oscan seems to have contributed to reducing their use (Adams, 2003, p. xix).

Another attitude is noticeable: Non-Latin speakers seemed to accept the new Latin language alongside their old, without giving up the rules of their native tongues. This can be seen in inscriptions when names are maintained, for example. Sometimes, in accordance with the bilingual surroundings, people had two different names, as has been observed in Etruscan or North African gravestone inscriptions. Thus, names becoming more and more Latinate in the same family signaled an increase in the bearer's level of identification with Latin-language culture (Adams, 2003, pp. 213, 755).

Overall, Latin adopted a large number of words of Greek origin and, all over the Roman Empire, L2 speakers of Latin spoke it with accent and mastered it to different degrees. These forms of spoken substandard Latin—or so called Vulgar Latin—were the main foundations for boosting the development of Latin in non-native speakers. The bilingualism of ordinary people, and not only those who were literate, then, played an important role and became the foundation for the development of the precursors of the later Romance languages.

The Middle Ages

Medieval societies developed in a multilingual context and profited from sources in Arabic culture. The spoken languages were far from being unified or codified as they are today, but were open to the needs of practical purposes. Knowing several languages was seen as something useful, necessary for carrying out one's tasks, for trade, for communicating in church networks, and for governing. Educated people were at least bilingual with Latin as the main language of instruction. Scholars such as Raymond Lulle (ca. 1232–1316) knew Latin and Arabic, and wrote in Catalan and Occitan.

Multilingualism could be spread not only through erudition, but also via class distinctions, as in the case of the middle and upper classes in England after the Norman conquest of 1066. These classes had to learn and apply French. This kind of bilingualism was mainly diffused at the end of the 12th century, reaching—as Short (2009) calculates—not more than 15% of French–English bilinguals in the middle of the 14th century. In 1362 the opening speech of parliament was given for the first time in English rather than French. The population was mainly monolingual, the clergy trilingual with Latin (Short, 1980). The testimony of language-learning manuals (the oldest at our disposal dates back to 1396) shows that French at that time had to be learned anew for the special purposes of jurisdiction and administration (Kristol, 1995). Nevertheless, this early period of elite bilingualism left profound marks on much of modern English vocabulary.

Britain was multilingual in another, very practical, sense because of its vast trading activities: In its ports merchandise from all over the world was registered and, as in all great ports, people communicated in several languages and the creation of functional trade languages, with mixed lexical forms, was common (Trotter, 2003).

An example of how spoken vernaculars changed status and became languages of prestige can be seen in the social history of the old Southern Netherlands (with Flanders), which developed into a territory of great commercial and cultural prosperity, generating a highly diversified society in a cultural border region where three languages were socially accepted. Latin was used—as elsewhere in Europe—for all written purposes up to the 11th or 12th century. The awakened self-consciousness and rise in social status of the merchant classes elevated the spoken (and not yet standardized) “vernacular languages” all over

Europe into a more prestigious position: In Flanders, for example, French was used as well as Dutch as the *lingua franca* in the courts and in literature from the 12th century onwards. Vernacular languages appeared later in administrative texts too, contributing to an overall intelligibility for a large population, since mastery of Latin was increasingly restricted to the clergy (who favored it for some centuries). Documents, then, could be written in two languages. The spoken vernaculars (Italian, English, French, and German, for example) were generally more suitable than Latin for the practical purposes of international medieval commerce (Prevenier & de Hemptinne, 2005).

It was not only in this time and in this part of the world that merchants were among the most multilingual people. It was quite common for young merchants to spend time in another city, learning the necessary new language “hands on.” Traces of this practice can be seen in learning materials, as documented for example by a collection of dialogues in Venetian and Bavarian dating from 1423 (Rossebastiano Bart, 1984). Also in the 13th to the 14th centuries we know of similar didactic dialogues which were used in Novgorod and Hamburg, aiming to sustain the acquisition of German and Russian. As in other parts of the world, it was simply a prerequisite in the Hanseatic League (a trade alliance extending along the Baltic and North Sea) for successful trade activities to have linguistically skilled merchants (Braunmüller & Ferraresi, 2003).

Dialogue books, grammars for language learning in five, six, or more languages, and polyglot dictionaries were diffused not only for erudition, but also in pocket format, apparently for those who traveled (Hüllen, 2005; Considine, 2008). The topics in the latter books clearly reveal their practical purpose: Conversations that include negotiations, pricing, sales discussions, asking for addresses, and so on show the necessity to be directly in touch with people in the relevant trade places. The learning of several languages at that time does not seem to have been so uncommon (Franceschini, 2002).

An attitude grounded in practical thinking can also be seen in the Golden Bull decree of 1356 in Nuremberg, where Emperor Charles IV advised the princes to have a multilingual education so that they would be able to rule their land with more political intelligence. He recommended that the sons of the Prince Electors, already strong in German, learn Latin, Italian, and Czech from the ages of 7 to 14, for the same reasons (Schneider, 1996, pp. 74–75). We know from the first emperors of the Habsburg dynasty how many languages they mastered: The first language of Maximilian I (1493–1519) was German, his most important L2 was French, and he also mastered Flemish, Italian, and Slovenian, and to some extent also English, Spanish, Latin, and Czech. The mastery of four to five languages was the minimum for emperors right up to relatively recent times (Goebel, 1997, p. 112).

Another revealing example of the management of several languages in bilingual or multilingual cities or regions is the city of Fribourg/Freiburg (Switzerland), situated in the French–German transition zone. In the 14th and 15th centuries five language varieties were used in spoken and written communication: Latin, French, Francoprovençal, German, and Swiss German (Alemanic). Hybrid forms were regularly used, with a high degree of interpenetration and widespread borrowing. Code switching between German, French, and Latin can be found in letters as well as in the minutes of the city council (Lüdi, 1985).

In literature, several forms of multilingualism were widespread in the Middle Ages: A poem could contain verses or strophes in different languages (as in Raimbaut de Vaqueiras’ *Descort*), without explanation. In a sort of fusion, languages were used in an intertwining manner in literary or scientific texts too; one can imagine that this also happened in speech. In terms of an approach to multilingualism, these practices are signs of a non-purist attitude with respect to the mixing of languages and emphasize the crucial role of overall multilingual practices in the Middle Ages up to the 16th century.

So, for centuries, multilingual abilities were not highlighted because they were simply normal for doing a job well (see also Braunmüller & Ferraresi, 2003, p. 3). Nor was perfect

command of a language an issue, as it is in contemporary discourse. We can assume that functional multilingualism was seen as the norm, and that non-ideological, pragmatic attitudes prevailed. Attempts to enforce one language in connection with state power were not very pronounced. Enemies were made, but not because of language differences. The seizing of linguistic differences in order to create hostility emerges very clearly later, when the idea of a pure and unified nation is raised. The ideology of the nation-state began to emerge slowly over the next centuries, giving colonialism its roots.

Moving On to Early Modernity and the Rise of the Nation-State

In terms of multilingualism, the period of the Renaissance (15th to the mid-16th century) was characterized by the attempt of humanists to return to pure Latin and Greek, after the decline—in their view—during the Middle Ages. This negative attitude toward the “Babel-like,” mixed use of languages or the autonomous development of Vulgar Latin in the Middle Ages opened the way for the search for a pure form, as well as for a monolingual and nationalistic ideal (fully developed in modern times through romanticism and nationalism). In the same way, spoken regional languages were codified, which means that a certain homogenization took place due also to the necessity to have unifying norms when printing books (increasingly available from the beginning of the 16th century) (Burke, 2004). Nevertheless, mixed texts did not completely disappear, but achieved another status in an exceptional sphere.

The age of Enlightenment (mid- to late 17th and 18th century) brought language learning into focus as a subject to learn by following rules: Increasingly grammars of single languages were written and therefore standardized. The basis of many new, empirical sciences was established in this period. Rationality was highlighted. Homogenizing, purist attitudes began to prevail. The Académie Française, for example, was founded in 1635 and had to guarantee the purity of the French language, thus avoiding influences from other languages. Learning “foreign” languages was an objective to achieve by learning in a guided way, and attaining perfection was perceived as more desirable than pragmatic, functional mastery. Against this background, one could be proud to know another language perfectly, as can be seen in the reports from Frederick the Great of Prussia (1712–86), who ostensibly showed his fluency in French and wrote it on a daily basis, not only by corresponding with Voltaire (Petersilka, 2005) and Goethe, but also by writing letters in French to his sister.

Apparently, multilingualism was no longer part of a self-evident practice but was seen as an exceptional competence. A divide can be seen: Learning other languages came under control, and either became an achievement for the elite (like French in the courts of Russia in the 19th century) or was relegated to socially excluded minorities and disregarded.

From the 19th century on, the formation of nation-states was carried out in an overall ideology of cultural homogenization, where multilingual communities were forced into monolingualism. The Habsburg Empire was a noticeable exception to this rule, not seeking to unify linguistically but pursuing a pluralistic language policy. From the time of Empress Maria Theresa’s school reform of 1774 onward, lessons could also be held in the respective native language of the children. Foreign languages were taught according to local conditions and requirements. The use of foreign languages in school was due to the commitment to the ideals of the Enlightenment, not only to show respect to minorities. In a special school model (“*utraquism*”), different subjects could be taught in different languages in primary schools; today we would perhaps call them CLIL-schools.

German in the Habsburg Empire was not institutionalized as a state language, and assimilation was not explicitly intended. Thus, in the constitution of 1867, all languages

spoken at the time were considered equal, schooling in the mother tongue guaranteed. However, another article clearly stated that no nationality should be forced to learn the language of another and, as a result, *utraquist* schools were gradually replaced by more monolingual “nationality schools.” Toward the end of the empire (1919), nationalistic ideologies prevailed and destroyed the efforts for coexistence between ethnic groups (Rindler-Schjerve & Vetter, 2007, pp. 56–9).

Among highly multilingual groups, we have to mention Jews as an outstanding multilingual community: Persecutions, expulsions, and opportunities have scattered the Jews around the world and they have protected their roots fiercely despite the influences of other languages and cultures. Such experiences have enabled Jews to be important mediators and translators, to be flexible, and to have a sense of relativity toward language and culture. In new territories, varieties of Judeo-Arabic and Judeo-Greek were developed by the second generation for in-group communication. In modern times, in Eastern Europe, for example, a repertoire could include languages from three different language groups: Semitic, Slavic, and German. Hebrew and Aramaic were used alongside local dialects and the language of power (such as Polish, Russian, Czech, German, or today English). Yiddish can be traced back to the end of the first millennium as a fusion language of the Ashkenazim, where German, Hebrew, and Russian, for example, can be merged into one word, as in *Shlimezalník* ‘an unfortunate person’ (*schlim* + *mazl* + *nik*). Preserving the “Holy tongue” (written Hebrew and Aramaic) in the core of their repertoire, it was an “essential multilingualism” (Harshav, 2008) that enabled the Jews to maintain essential common cultural traits.

From the early 19th century on, the prevailing ideological discourse in Europe has tied together the notions of nation, language, and identity. The standardization process which began for practical purposes (such as that of the new book-printing techniques in the 15th and 16th centuries) became ideological. National languages became fixed and the “pure use” of them was seen as the only attainable mastery, which had the effect of stigmatizing those who spoke with an accent, and bi- and multilingual people in general (Braunmüller, 2007). By tracing sharp national boundaries and postulating nations with only one national language, nationalism creates language minorities. In modern nation-states all over the world, overt or covert suppression of minority languages was (and is) all too common (Thomason, 2001).

Linguistic Diversity in the Former Colonial World

South America shows a high linguistic diversity with respect to other countries (highest in the Pacific): Due to migrations, population displacements, and colonization in modern times, the language diversity pattern in South America shows a discontinuous, patchwork-like image. A functional divide between indigenous languages and the languages of the European colonialists seems to be typical, as is the assimilation of the European languages: During the Inca expansion, interrupted by European colonization from the 16th century onward, Quechua had the function of a *lingua franca* in vast areas of the Andes, and other populations adapted it, or shifted to it definitively. European colonization then became intrinsically linked to Christianization, for which priests initially tried to use the indigenous languages. Grammars of local languages were written (the first for Quechua in 1560). The overall language policy was one of assimilation, clearly from the 17th century on, with widespread attitudes of devaluation of the indigenous languages on the part of the colonizers. A high number of linguistic groups became extinct during the colonial period. In the territory of Ecuador, for example, only a dozen of the 30 or so languages known to have been spoken at the time of the conquest were maintained (Hornberger & King, 2001).

The African continent also figures among places with high scores in linguistic diversity (around 250 languages are currently spoken in Nigeria, for example); one can imagine

that it was not very different in the past. Due to the presence of multiple home languages (through intermarriage, for example) and the use of a huge amount of lingua francas (like Wolof and Krio) for practical reasons, there seems to be a rooted pattern of individual multilingualism in Africa; moreover, for those who are educated or living in major cities, a colonial language (French, English, German, or Dutch) can enter the repertoire. Languages are seen as a resource, as a necessity for practical action (Adebija, 1994).

Colonial languages were imposed as official languages by the colonial powers in Africa and South America, but also in other parts of the former colonial world such as India, and they often maintained this position even after such countries gained independence in the 20th century. The social repertoire of these societies often includes a supranational language or a language of international communication, usually the language of a current or former colonial or cultural power, which covers the spheres of science and culture and is complementary to the national languages. Despite this powerful umbrella function, the inherited patterns of multilingualism can be preserved, as is the case today in India, Pakistan, Bangladesh, and Nepal, which have been multilingual countries from the time of their earliest recorded history (Kachru, Kachru, & Sridar, 2008).

Worldwide Lines, Forces and Tendencies

From the above examples, the main lines and general driving forces behind multilingualism in history emerge as follows:

1. Multilingualism is seen as a social phenomenon and as a capacity of individuals or groups which can be best studied in contact situations. These are more likely in regions with high language *diversity*, which is greatest in the Pacific area and in the "New World," and lowest in the "Old World." Because the available historical documentation shows the inverse pattern, we found our observations were still biased.
2. In contact situations, the need to cope with multilingual communicative situations is pressing. The *strategies* used seem to have been widespread in the past and include help from translators, sign languages, creating functional trade codes, partial (or total) acquisition of the other language in speaking and writing.
3. When language contact goes along with the establishment of *power* (conquests, for example), hierarchies of prestige prompt speakers to adopt a new language. However, it does not follow from this that the original languages disappear as a rule. Languages can coexist and be preserved despite the presence of continuing political forces.
4. Establishing explicit language *policies* is a relatively new practice. Fluid, pragmatic choices were almost common in the past in Europe and prevail in highly diversified societies.
5. The *ideological overload* with respect to languages as identity markers and symbols of nations is more typical of modern times, with special focus on the Old World.
6. *Codification* comes along with technical development, administrative needs, and the necessity for widespread communication. It produces homogenization in a variable, regional use, as well as a divide between the written and spoken language.
7. Partial, *functional command* of several languages is the main rule in multilingual practices and was more accepted in the past, and more prevalent outside the Old World.

History of Translation

JUDY WAKABAYASHI

The Object of Inquiry

Translation historiography explores changes in the practice and conceptualization of translation over time and space, as well as the causes of these changes. It helps contextualize the practices and ideas of the past, relativize those of the present, and identify regularities, interconnections, turning points, and advances. Studies of translation history are not a new phenomenon. Yet only recently has this emerged as a subdiscipline that draws on insights and methodologies from both translation studies and historiography but that has an “awareness that translation history might actually have a method, with its own concepts, procedures and results” (Pym, 1998, p. 13). Translations and translators are influenced by and can influence their communicative context, and they have had an important impact in the following main areas of cultural history suggested by Delisle and Woodsworth (1995): the invention of alphabets, the development of languages, and the writing of dictionaries; the emergence of national literatures and the shaping of their form and content; the creation and dissemination of knowledge; the power relations between different regions and countries; the practice and spread of religions; and the transmission of cultural goods and values, a category that “permeates and is permeated by” all the other domains (Neubert, 2001, p. 188).

This has led to two complementary approaches to the relationship between translation and history: (a) “what can translation mean for the understanding of history, in particular of cultural practices” and (b) “what can history mean for the understanding of the multifarious forms of translation (a process, a product, a trope, an institution, a theory, etc.)” (D’hulst, 2010, p. 397). Historians such as Rafael (1988) and Howland (2002) have focused on the former approach (translation *in* history or history *through* or from the perspective of translation), but most translation scholars focus on the history *of* translation. Virtually any aspect of translation—for example, its processes and products and their relationship with the sociocultural context, the lives and work of translators, translation theories, translator training, workplace structures, the impact of institutions and technology—can be examined from a historical perspective. Yet the focus has long been on the textual level at the expense of processes (e.g., canonization, the use of translations), the discourses surrounding translation, or the human, professional, and cross-cultural (rather than nation-based) aspects. Within this focus on textual aspects there has also been a privileging of canonical literary and religious works, to the neglect of other genres (e.g., popular literature and official or commercial texts) and translations that did not identify themselves as such.

Research Questions and Source Collection, Evaluation, and Interpretation

The approach to “doing” translation history depends on the subject matter and research question. Broadly, however, Lambert (1993, pp. 13–14) advocates combining a focus on

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

© 2013 Blackwell Publishing Ltd. Published 2013 by Blackwell Publishing Ltd.

DOI: 10.1002/9781405198431.wbeal0512

internal questions about how particular translators proceed with a focus on *external* questions about the context in which these translators work. The hypotheses guiding the research need to be examined on the basis of the data so as to corroborate, refine, or refute them.

Both in relation to historical theories and practices, the data search—what Pym (1992, p. 3) calls translation archeology—can usefully focus around the questions of “who,” “where,” “what,” and “when” (and the reverse questions of “who *not*,” etc.), alongside translation criticism (“how” and “how *not*”). Thought-provoking sample questions can be found, for instance, in Delabastita (2005, pp. 35–8), D’hulst (2010, pp. 399–403), Lambert (1993, pp. 11–12), St-Pierre (1993, pp. 66–8), and Woodsworth (1998, p. 101). Relevant primary sources (those originating in the period under study) range well beyond source texts and translations (including successive drafts and re-editions with textual variants) to include, for example, comments by translators, patrons, and critics; publishers’ documents; documentary evidence of reader reactions; manuals for training translators; contracts and court records; business records and statistics about the language industry; client-generated instructions; personnel records; eyewitness accounts; paratextual and visual sources such as book covers and paintings of translators; and comparable original texts in the target language. Secondary sources (whose distinction from primary sources is not always clear) include, for example, bibliographies of translated works (and analogous bibliographies of nontranslated works), biographies of translators, descriptions of past translation theories, reviews of past translations, and accounts of translator-training institutions of the past.

Critical evaluation of sources involves considering their authenticity, scope, and quality; the sociocultural and mental context of their production; the audience; the intended and actual purpose; the author’s credibility and stake in controlling the narrative; any biases, assumptions, omissions, and internal or external contradictions; the surface and deeper meanings; the use of language to lead readers to a particular conclusion; whether terms used have a different meaning from today and from the apparent equivalent in the historian’s language; and any subsequent intervention by editors or compilers.

Yet quantity and quality of historical data are not enough. The nub of the historiographical enterprise lies in testing hypotheses against the evidence, interpreting and explaining the facts and forces—focusing on the “why” and “with what effect” (Pym, 1992, p. 3)—and arranging the data in a systematic and meaningful narrative. It should also be noted that historiographical methods are to some extent culture-specific—for example, East Asian translation historians tend to emphasize documentary research over theoretical approaches, which Sato (2002, p. 128) notes are “a highly Western tradition.”

Writing Translation History

The writing of translation history involves arranging evidence in a form that transcends simple sequential description—that is, in a connective narrative that is composed on a thematic, concept-led, or other meaningful basis and that infers links among the facts so as to produce an explanation of the hierarchy and interaction of significant direct and indirect causes (e.g., chance; the actions of individuals; large-scale practices, processes, and structures such as colonization, migration, the introduction of printing) and the consequences. The writing process is shaped not only by the available data but also the historian’s assumptions and methodology, potentially leading to differing interpretations. Translation historians can learn from the growing awareness among historiographers that the narrative is not a neutral reconstruction of reality or *the* past, but *one* possible construction (representation) filtered through the sources and the historian’s present-day “situatedness,” (pre)conceptions, and interpretations, even when attempts are made to perceive the past on its own terms. Postmodernism has made historians more attentive to their subjective position and the language and rhetoric in their own writing and the records, as well as voices

that have gone unheard because they are excluded from power. Constructing an ordered narrative provides explanatory coherence, but it has the potential for manipulating the facts and argument in line with a preconceived outcome or ideological position, so it is vital to interrogate our intentions, assumptions, inferences, criteria of proof, and choice of categories and narrative form and to acknowledge evidence that fails to fit the hypothesis. Master narratives (e.g., imperialism, nationalism, modernization, market forces) that attempt to integrate and give meaning to long-term events and phenomena as part of a purposeful development have attracted criticism as being artificial, antihistorical, and overreaching yet restrictive.

One counterbalance to all-encompassing grand narratives is to provide diverse and more complex perspectives through microhistory (see Adamo, 2006), which reduces the scale of observation to a close-up focus on very specific and either typical *or* atypical texts, episodes, locations, phenomena, topics, groups (e.g., diasporic language communities) or individuals so as to penetrate behind apparent uniformity. Microhistory is characterized by the detailed procedures, not the small scale, and it can be used on objects of any size, which are studied not in isolation, but in their context. This acts as a link between systems and the individual, to whom agency and the “livedness” of experience are restored. Microhistorians argue that the textured details connect the whole and that microanalyses can contain broad implications, revealing patterns that transcend the item under investigation while modifying macrohistory by highlighting apparent exceptions. Anomalies are regarded as a potentially rich “sign of a larger, but hidden or unknown, structure” (Peltonen, 2001, p. 349), and microhistories rise above anecdotal data because of the intensive examination of their verifiability and relevance. Ginzburg (1993, p. 24) argues that doubts, misrepresentations, hesitations, and silences—that is, the historian’s “search for truth” and the limitations of the evidence—must become *part* of the narrative account. Microhistory helps counter excessively theoretical abstraction, and facts or phenomena are easier to prove or refute with this approach. Potential disadvantages include the lack of representativeness (although generalization is not regarded as a significant goal of microhistory) and the overlooking of larger patterns and different contexts. These drawbacks can be overcome by accumulating microhistories and regarding the micro and macro as complementary.

One aspect of the writing of history that distinguishes it from mere chronicles is periodization, but this is often uncritically based on homogenizing or largely arbitrary constructs such as centuries, eras (e.g., dynasties or reigns), or periods (e.g., ancient, medieval, modern). These are often related to broad cultural history (e.g., the Renaissance), major periods in national (rather than cross-cultural) history (e.g., China’s Cultural Revolution), literary currents (e.g., the Romantic period), or generic categories (e.g., the novel). Although ideas and practices of translation are affected by external forces in the source and target cultures, a more appropriate periodization would be based on processes, movements, events, and texts more directly relevant to translation itself (e.g., whether verse was rendered as verse or prose). Some scholars (e.g., Steiner, 1975, pp. 248–50; Chesterman, 1997, p. 20) have proposed periodizations of translation, but it is important to note that periodizations are specific to particular translation traditions. It is also vital to recognize the coexistence and interaction of long-term, midterm and short-term periods in translation history and to consider the need for periodizations tailored to more specialized histories, such as that of women translators or translation theories.

Sample Approaches to Translation History

Although translated works might in a sense be viewed as historical “events” (especially, for instance, when a translator adopts an innovative approach), one feature of translation history is its text-based rather than event-based nature (alongside its translator-centered,

interlinguistic, and cross-cultural aspects). Hence methodologies focusing on texts—for example, literary historiography, bibliometrics—are instructive for translation historians. Book history, with its focus on the physical object, is relevant in such areas as the impact of material causes (e.g., increasing literacy, mass production of paper, the transition from manuscripts to the print medium, the invention of computers) in allowing quicker production of translations, broader dissemination, and greater longevity and in arresting textual and linguistic drift, thereby bolstering the ideal of accuracy. Focusing on books does, however, neglect translations appearing in other influential forms such as newspaper or periodical serializations.

Lambert (1993, p. 6) regards descriptive translation studies as “one of the most explicit indications of the rediscovery of history in Translation Studies and hence of the development of a new type of historiography.” Nevertheless, Pym (e.g., 2009, pp. 24, 28) has criticized the descriptive (rather than explanatory) and purportedly objective focus of descriptive translation studies, and he argues (1998, p. 115) that focusing on translation norms emphasizes stability at the expense of change or conflict. Pym (1998, p. 112) advocates focusing on debates (between people, or contradictions between actual translations and what is said about translations) as indicators of tension or conflicting norms (and hence possible change). This focus on disagreements is potentially more useful in raising questions than is Pym’s own concept of regimes (1998, pp. 125–42), which focuses on shared aspects. Pym (2009, p. 35) also critiques Toury’s notion (1995, p. 12) that translators operate primarily in the interests of the target culture, with the target culture governing their decisions. Instead Pym argues that translators themselves can help shape the target culture, and he proposes the notion of professional interculturalities, whereby translators can work in locations influenced by more than one culture and functioning “as a cultural space with its own membership rites, norms of behavior, ideologies and ethics” (2009, p. 38). Prosopographical study of any collective characteristics (biographical and otherwise) that define translators as an occupational group, as well as their relationships and activities, might provide insights into professional interculturalities, although this concept does not account for the not uncommon historical situations where translators worked in virtual or comparative isolation from each other.

One relatively neglected area is the history of the reception of translations—macroanalytical and microanalytical studies of who read what translations at different times and places and, more importantly, how and why they were read (for pleasure, curiosity, self-improvement, etc.). In the past translations were not necessarily read in the same ways as today—for example, they might have been read aloud or collectively; their scarcity might have enhanced their value; or readers might have regarded translations as a whole as harmful to the receiving culture. Readers’ contacts with and responses to translation(s) are evident through text selection guides; what translated works readers owned or borrowed from libraries; their diaries, memoirs, letters to publishers or translators; marginalia written in translations as an indicator of interpretative strategies; contemporary depictions “in fiction, autobiographies, polemical writings, letters, paintings, and prints” (Darnton, 1992, p. 152); censorship records; and school curricula. Much work remains to be done on past ideals and assumptions underpinning the reading of translations. As Darnton (1992, p. 142) notes, however, “the documents rarely show readers at work, fashioning meaning from texts, and the documents are texts themselves, which also require interpretation.” Historians could also usefully study how the reading of translations has affected history—Darnton (1992, p. 161) cites Mao’s reading of Marx as an example.

Since translating is a social (not just textual) practice, another approach to translation history is to study changes in the relationships among social agents (e.g., translators, authors, clients), structures (e.g., political, economic, legal, religious, training, educational, and professional conditions and institutions), and processes (e.g., urbanization) and the

creation and reception of translations. Wolf (2010, p. 341) suggests a variety of sociologies—of agents (e.g., how translators are socialized by norms), of the translation process, of the cultural product, and even of translation studies itself. There is an increasing number of studies of translation sociology (e.g., Pym, Schlesinger, & Jettmarová, 2006; Wolf & Fukari, 2007), although not always from a historical perspective even though sociological issues are amenable to historical study. One approach is to focus on largely neglected groups, such as the history of nonliterary translators. In historiography as a whole, however, there has been a move away from the tendency to view individuals “as products of the systems to which they belonged” (Howell & Prevenier, 2001, p. 115), with greater emphasis being given today to cultural and intellectual history. Nevertheless, Wolf (2010, p. 342) argues that social and cultural practices are inextricably connected “in terms of power, ideology,” and so on.

The intellectual history of translation examines the production, changes, and migration of discourses (theoretical, philosophical, critical, literary, academic, social, institutional, methodological, popular) on translation across time, space, and contacts with other disciplines or under the effect of external constraints. D’hulst (2010, p. 400) points out that theories are not the only mode of reflection on translation (alternatives include prefaces and criticism, for instance) and that the theory-oriented approaches dominating historical research in recent decades are underpinned by a problematic, teleological view of history “as a means to highlight the ‘progresses’ of translation theory.” In turn Pym (1998, p. 10) warns that “The focus on theory can thus become a way of producing explanations so powerful that they effectively obscure the complexity of the past, particularly when historians overlook the strategic and frequently defensive roles played by theorization.” D’hulst (1995, p. 19) argues that the primary aim of the historian of translation theories is their optimal reconstruction according to the viewpoint of those who conceived them and the viewpoint of their users. This relativistic stance should not, however, preclude the incorporation (but not imposition) of insights from a contemporary perspective, which are “complementary and not substitutive” (D’hulst, 1995, p. 33). Beyond the theories themselves, it is also important to examine their reception and impact (e.g., among translators, translator trainers, scholars of translation), that is, their relationship with translation practices and the surrounding discourses.

One key debate focuses on the respective roles in translation history of individuals (e.g., theorists) and systems or forces operating at the level of groups, societies, or even “universal laws.” The latter and currently more dominant approach is associated in particular with descriptive translation studies, but has attracted criticism for treating translators as subordinate to institutions or norms (even if this subordination takes the form of resistance) and for overlooking “the agency of translators themselves who can decide to flout rules, invent translation strategies, and inject all sorts of unpredictable elements into translations” (Tymoczko, 2007, p. 183). Awareness of the role of individuals has led Pym (2009, p. 45) to propose a humanizing approach—not as a strict methodology, but as “a mode of asking questions that may lead to unforeseen answers.” He argues (2009, pp. 32–6) that studying translators allows researchers to unearth the obscure, follow the multidiscursive (how translators brought together the different professional discourses in which they participate in the receiving system, such as translating, writing, editing, publishing, teaching), accept translators’ multiple allegiances (not just to the target culture), and trace their movements. Pym (2009, p. 37) maintains that translatorial subjectivity can be revealed more directly “by asking biographical and sociological questions, or looking critically at the language in prefaces, correspondence and the subject’s texts other than translations,” without resorting to “intricate textual criticism.” Crisafulli (2002, p. 40), however, advocates a composite approach of considering the translator’s biography and declarations of intent and assuming that “the translator’s outlook will surface at specific

sensitive points of the target text (including paratexts)" in the form of modifications or interpretations based on this outlook.

An alternative that transcends the structure/agency debate is the study of the interaction between individuals and transindividual factors in translation history. One way of connecting individuals and systems is Pierre Bourdieu's categories of *habitus* (dispositions "acquired by individuals through experience and socialization," Wolf, 2010, p. 339), *field* (the "social positions occupied by individuals and institutions," Wolf, 2010, p. 339), and *capital* (economic capital, social capital in the form of networks, cultural capital in the form of education, knowledge, etc., and symbolic capital in the form of prestige). For instance, D'hulst (2010, p. 402) suggests that the *habitus* or "coming into being" of translators (and related agents) can be studied from perspectives such as "intellectual and social backgrounds (training, gender, socio-economic, ideological and cultural profile), production (translational, critical, authorial etc.), group formation and network relations" (D'hulst, 2010, p. 399).

The study of synchronic professional interculturalities overcomes the monocultural tendency in Bourdieu's concepts and lends itself to actor-network theory (see Buzelin, 2005) or social network analysis. Although an offshoot of systems theory, social network analysis crosses national and other boundaries to look at:

how relationships, especially social pressures, around a person, group, or organization affect beliefs or behaviours. . . . it sidesteps the discussion whether change was "external" or "internal". It focuses attention away from "cores" and "peripheries". . . . it accepts that actual networks overlapped, changed, and decayed. Perhaps most importantly, it puts real people back into . . . history, rather than only rises and falls, trends, movements, and developments. (Gordon, 2008)

A similar approach can be applied not only to professional networks among translators but also to intellectual networks among translation theorists, despite the greater difficulty of demonstrating intellectual contacts and influences. Gordon (2008) recognizes that social network analysis "does not handle change well unless one can do repeated iterations of the net over time," so he concludes that it needs to be undertaken in conjunction with other approaches.

Quantitative approaches help contextualize qualitative studies of translation history, providing a counterbalance to the frequent focus on canonical works or famous translators by capturing a broader picture that can include more commonplace and peripheral translations or individuals. Quantitative methods (e.g., cluster analysis, time series analysis) can handle greater masses of data and allow more rigorous testing of hypotheses, leading to more valid and precise conclusions and helping to reveal blank spaces as well as patterns, tendencies, and relationships that go beyond chance. These approaches can also raise new questions, revise traditional periodizations, and facilitate comparisons. Yet not all research questions in translation history (e.g., theories) involve quantitatively measurable or categorizable indicators, and quantitative data are not always available or of sufficient historical significance to merit study. Other problems include lack of representativeness or comparability, distortions (e.g., census figures probably do not include part-time and freelance translators), the mechanistic and impersonal focus, the reductionist nature of statistical categories, and the need for training and often collaboration on the part of researchers. As with qualitative approaches, it is essential to proceed to careful explanation and interpretation of the data. Although quantitative approaches to historiography failed to live up to initial expectations, there has been some revival recently in response to overly theoretical postmodern approaches, and translation historians could benefit from further exploration of such approaches. Ultimately, however, any method is justified only if it produces superior results, and quantitative methods might be best suited to providing

supportive evidence for qualitative approaches rather than acting as “the foundation stone of a whole argument” (Hudson, 2000, p. 20). A combination of methods can offer a more holistic perspective and help compensate for any drawbacks of individual approaches.

Toward Integrative Translation History

Little has been written about the conceptualization and methodology of comparative translation historiography, perhaps in reaction to the dangers of sweeping comparisons or because of practical difficulties arising from the need for expert knowledge of more than one translation tradition. Nevertheless, much can be gained by tracing the (dis)continuity of translational practices and ideas across cultures. Once any parallels have been identified, the next step is to determine whether there is a causal connection and why. An even greater contribution to the field can be made by identifying practices and ideas that are *without* parallels elsewhere. Comparative studies are a step toward what Woodsworth (1998, p. 104) calls a “rejoining of the pieces”—a task that calls for collaboration.

History of World Englishes

BRAJ B. KACHRU

Introduction

The history of the construct of “World Englishes” (WE) has evolved over a short period of not more than five decades. It was in 1978 that two path-breaking, independently organized conferences were planned in two parts of the USA.

The first two-week conference organized by Larry E. Smith at the Culture Learning Institute of the East-West Center in Honolulu, Hawaii, took place in April. It was followed by a three-day conference in June–July organized by Braj Kachru in conjunction with the Linguistic Institute of the Linguistic Society of America hosted by the University of Illinois at Urbana-Champaign in the USA. The two conferences were ideologically almost identical. They shared like-minded participants from major English-speaking parts of the world except that the Honolulu conference did not have any participants from Africa.

At the end of the Honolulu conference, Braj Kachru and Randolph Quirk (1981) described it as a “unique learning experience”:

there were almost as many varieties of English—native and non-native, western and non-western—as there were participants . . . all of them used the English language to debate, discuss, and argue questions which concern both native and non-native users of English, as well as the global uses of English in various sociolinguistic contexts in different parts of the world. (p. xiii)

The participants at the Honolulu conference included Christopher N. Candlin (Lancaster), Ruth Crymes (Honolulu), M. L. Boonlua Debyasuvarn (Bangkok), Randolph Quirk (London), Jack C. Richards (Singapore), H. H. Stern (Toronto), Peter Strevens (Cambridge), Mayuri Sukwiwat (Bangkok), Mary W. J. Tay (Singapore), Irene F. H. Wong (Kuala Lumpur). The Illinois conference, like the Honolulu conference, “broke the traditional pattern of such deliberations: no inconvenient question was swept under the rug. The professionals, both linguists and literary scholars, and native and non-native users of English, had frank and stimulating discussions” (Kachru, 1982, p. xiii).

The issues related to English were discussed in divergent linguistic and cultural contexts and realistic generalizations were made using relevant empirical data. The Illinois conference was primarily attended by English specialists from Africa, South Asia, East Asia, and from the Inner Circle of English. The participants included Ayọ Bamgboṣe (Nigeria), Elinor G. Barber (Ford Foundation, New York), Eyamba G. Bokamba (Illinois), Charles A. Ferguson (Stanford), Joshua A. Fishman (New York), Melvin J. Fox (Ford Foundation, New York), Shirley Brice Heath (Stanford), Yamuna Kachru (Illinois), Henry Kahane (Illinois), Peter H. Lowenberg (California), Rodney E. Moag (Texas), Cecil L. Nelson (Indiana), Larry E. Smith (Honolulu), S. N. Sridhar (Stony Brook, New York), James Stanlaw (Illinois), Peter Strevens (UK), and Edwin Thumboo (Singapore). In retrospect, one might say that the Hawaii and Illinois conferences

blazed the trail for a new approach which provides a realistic framework for looking at English in a global context, and for relating concepts such as appropriateness, acceptability and intelligibility to the pragmatic factors which determine the uses of English as an international or intranational language. (Kachru & Quirk, 1981, p. xx)

These conferences provided insightful new direction with an unparalleled assembly of scholars. WE colloquia were organized in cooperation with Teachers of English to Speakers of Other Languages (TESOL); once with the International Association of Teachers of English as a Foreign Language (IATEFL) in Belgium; and twice with the Georgetown University Round Table on Languages and Linguistics (1986 and 1987; see Lowenberg, 1988).

In August 1986, yet another conference was organized, again at the East-West Center, Honolulu, with focus on "Language and power: Cross-cultural dimensions of English in media and literature." The aim of this conference was to explore the concept of linguistic "power" and of English with a cross-cultural perspective; and to provide data for the study of such "power" from various English-using countries in the domains of literature and the media (film and journalism).

In 1988, an interim committee met at the International TESOL Convention in Chicago and unanimously agreed to the formation of the International Committee for the Study of World Englishes (ICWE).

Formation of the International Association for World Englishes (IAWE)

In April 1992, the ICWE met at the University of Illinois at Urbana-Champaign as a cosponsor of a conference on "World Englishes Today." The conference also celebrated the formal launch of the International Association for World Englishes (IAWE). Since then, the presidents of IAWE have been elected from a variety of countries: Larry E. Smith (1993–6), Braj B. Kachru (1997–8), Anne Pakir (1998–2000), Ayò Bangboşé (2001–2), Kingsley Bolton (2003–4), Margie Berns (2005–6), Bertus Van Rooy (2007–8), Daniel R. Davis (2009–10), and Zoya Proshina (2011–12).

The location of each conference indicates IAWE's international profile: University of Illinois at Urbana-Champaign; International Center, Nagoya, Japan; East-West Center, Honolulu, Hawaii; National University of Singapore; Tsukuba University, Japan; Portland State University, Oregon; University of Potchefstroom, South Africa; Syracuse University, New York; Purdue University, West Lafayette, Indiana; Chukyo University, Nagoya, Japan; Regensburg University, Germany; City University of Hong Kong; Linguistic Society of the Philippines, Cebu, Philippines; Simon Fraser University, Vancouver, Canada; Monash University, Melbourne, Australia.

In August 1994, IAWE crossed the borders of the Western world. The first East Asian conference was organized at Chukyo University, Nagoya, Japan, under the directorship of Sanzo Sakai.

World Englishes and "WE-ness"

The concept of World Englishes has multiple constructs, yet it is agreed that the term "symbolizes the functional and formal variations, divergent sociolinguistic contexts, ranges and varieties of English in creativity, and various types of acculturation in parts of the Western and non-Western world" (Kachru, 1997, p. 212). This concept emphasizes what may be characterized as "WE-ness." The dichotomy between *us* and *them* (the native and non-native users) is not part of the construct of the language:

English is a valuable linguistic tool used for various functions. The approaches to the study of world Englishes, therefore, have to be interdisciplinary and integrative, and different methodologies must be used (literary, linguistic, and pedagogical) to capture distinct identities of different Englishes, and to examine critically the implications of such identities in cross-cultural communication and creativity. (Kachru, 1997, p. 212)

The time was right to reevaluate the exhausted theoretical and applied paradigms. These paradigms were imposed on what was termed the world of “non-native” Englishes. Consider, for example, the following 20 points: the spread and stratification of English; the characteristics of the stratification; interactional contexts of WE; the concept of WE; WE in diaspora; English-using speech communities across cultures; dynamics of English-using speech communities; conceptual frameworks and WE; the bilingual’s literary creativity and canonicity; multicanons of literatures in WE; nativization and Englishization; fallacies about users and uses; monolingual paradigms and heteroglossic Englishes; the power and politics of English; codification and authentication; the gate-keepers of the sacred cows; the faces of hegemony; the genres of atonement, guilt, and lies; Caliban’s weapons; teaching WE. (These 20 points are discussed in Kachru, 1997, pp. 213–37.)

The overused and misleading concepts of “native” and “non-native” are functionally un insightful, particularly in multilingual social contexts. A fitting answer to the “native speaker” myth, and the function of “native speaker” in pedagogy and research, is given by the late Charles A. Ferguson in these words:

Linguists, perhaps especially American linguists, have long given a special place to the “native speaker” as the only truly valid and reliable source of language data, whether those data are the elicited texts of the descriptivist or the intuitions the theorist works with. Yet much of the world’s verbal communication takes place by means of languages which are not the users’ “mother tongue,” but their second, third, or *n*th language, acquired one way or another and used when appropriate. (Ferguson in Kachru, 1992, p. xiii)

The Three Concentric Circles and World Englishes

At the 50th anniversary of the British Council in London in 1985, the diffusion of World Englishes (without using the term WE) was explained in terms of the *Three Concentric Circles*: the Inner, Outer, and Expanding Circles. This characterization of the construct was not based on any hierarchical priority, or preferential ranking. It explains that:

The Inner Circle is *inner* with reference to the origin and spread of the language, and the Outer is *outer* with reference to geographical expansion of the language—the historical stages in the initiatives to locate the English language beyond traditional English-speaking Britain; the motivations, strategies, and agencies involved in the spread of English; the methodologies involved in the acquisition of the language; and the *depth* in terms of social penetration of the English language to expand its functional range in various domains, including those of administration, education, political discourses, literary creativity, and media. (Kachru, 2008, p. 568)

The *Expanding Circle* does not have a history of British colonization. This Circle is fast expanding in its use of English. It has developed numerous varieties (see Kachru & Quirk, 1981).

The term “Inner” Circle refers to a historical reality: a reality in the development of the language and its diffusion. The concentric circle representation

embodies a long historical context within which the English language has evolved, expanded, converged and altered to form distinct identities. The triad, it is explained, . . . takes into consideration their histories, the colonial designs, the linguistic manipulation within each circle, and the impact of colonial expansion and that of the Imperial Raj. The historical contexts of the Expanding Circle and the phases of the induction of English are not necessarily shared with the Outer Circle. (Kachru, 2005, p. 219)

The Three Circles have their distinct histories and functions for the English language. However, all the users of Englishes are integral parts of the World Englishes. In McArthur's concept, the Three Circles construct indicates "the democratization of the attitudes to English everywhere in the globe." In his view:

This is a more dynamic model than the standard version, and allows for all manner of shadings and overlaps among the circles. Although "inner" and "outer" still suggest—inevitably—a historical priority and the attitudes that go with it, the metaphor of ripples in a pond suggests mobility and flux and implies that a history is in the making. (McArthur, 1992, p. 334)

World Englishes: The Journal

The history of the journal *World Englishes: Journal of English as an International and Intranational Language (WE)* demands an explanation. The first issue of the journal *World Englishes* is marked volume no. 4 and issue no. 2. *WE* is a reincarnation of *World Language English* but has different aims and a different pedagogical agenda. It was published by the Pergamon Press at Oxford, UK. The editorial in the first issue of *WE* explains that "in its reincarnation *WE* represents a new idea, and a new credo. That explains the new name, the new format, and the new editorial board" (Kachru & Smith, 1985, p. 209). McArthur, commenting on *World Englishes* (1985) and its acronym *WE*, says that the logo:

serves to indicate that there is a club of equals here . . . The editorial board considers the native and non-native users of English as equal partners in the deliberations on users of English and its teaching internationally . . . the acronym *WE* aptly symbolizes the underlying philosophy of the journal and the aspirations of the Editorial Board. (1993, p. 334)

The first issue of *WE* was "dedicated with professional respect and personal affection to Sir Randolph Quirk, FBA."

In 2006 Kachru and Smith, after 21 years, passed on the responsibility of editorship of *WE* to Kingsley Bolton and Daniel R. Davis. Margie Berns also made admirable contributions during the two years when she was a coeditor with Daniel Davis.

Content Analysis of *WE*

The content analysis of papers published from 1985–2005 in *WE* shows the range of topics that the journal has covered (see Table 1).

The figures in Table 1 demonstrate that

on many issues, for example contrastive discourse analysis, the politics of English world-wide, the analysis of bilingual creativity, *World Englishes* has been a pioneer in opening up areas of inquiry that have later expanded into distinct fields of their own. (Bolton & Davis, 2006, p. 6)

Table 1 Contents of *WE* vol. 4(2) through vol. 24(3)

<i>Topic area</i>	<i>Number of articles</i>	<i>Percentage of total articles</i>
Discourse/genre/text	99	15.3%
The sociology of language	88	13.6%
Applied linguistics	83	12.8%
Areal studies	74	11.4%
Contact linguistics	63	9.7%
A “feature-based” approach	61	9.4%
Critical linguistics	56	8.7%
Bilingual creativity	55	8.5%
English corpus linguistics	18	2.8%
Lexicography	17	2.6%
World Englishes theory	14	2.2%
English studies	11	1.7%
Pidgin and Creole studies	8	1.2%
Total	647	100%

Bolton and Davis (2006) rightly emphasize that “a striking feature of the journal has always been the ability to break new ground and to expand the vision of our work as researchers and educators” (p. 6).

The journal *WE* raised three conceptual questions: What does the concept “Englishes” imply both theoretically and functionally? What are the demanding research areas that deserve immediate attention? And what is the intended readership on whom the journal should focus?

In 1985, Kachru and Smith provided an answer to these concerns in *WE* (1985, p. 210):

“Englishes” symbolizes the functional and formal variation in the language, and its international acculturation, in West Africa, in Southern Africa, in East Africa, in South Asia, in Southeast Asia, in the West Indies, in the Philippines, and in the traditional English-using countries: the USA, the UK, Australia, Canada, New Zealand.

We further emphasized that:

The language now belongs to those who use it as their first language, and to those who use it as an additional language, whether in its standard form or in its localized forms. The recognition of this functional diversity is so important that we have indicated it in the sub-title of *WE*. (1985, pp. 210–11).

The twentieth anniversary of *World Englishes* (2006) was a year of celebration. The following are the reflections of what some international scholars had to say (Alatis et al., 2006).

a. The journal *World Englishes* has become one of the most highly regarded publications . . . the acronym *WE* itself symbolizes the inclusiveness. (James E. Alatis, Georgetown University, Washington, DC)

b. *WE* has been a forum of rigorous, yet civil scholarly exchange based on inclusiveness and openness of dissenting voices and contradictory views from around the world. (Margie Berns, Purdue University, Indiana)

c. A very happy birthday to a dear journal that has helped me grow intellectually, opened my eyes to research areas akin to creolistics, broadened my conception of “language evolution under contact conditions,” trained me to see how differentially English has evolved in diverse settings, prompted me to rethink the meaning of the terms “colony” and “colonization” and to pay attention to the distinction between “colonist” and “colonizer,” and encouraged me to be more global and less parochial. (Salikoko S. Mufwene, University of Chicago, Illinois)

d. *WE* went global long before globalization was a buzz word. The editors were visionary in entering new scholarly territory, and the journal remains exceptional as a forum for a diversity of voices approaches. (Robert Phillipson, Copenhagen Business School, Denmark)

e. Congratulations to the editors on the splendid success of *WE*. This energetic and scholarly work over 20 years is rewarded by the international impact the journal has had. (Randolph Quirk, University of London and Gabriele Stein, Sprachwissenschaft, Heidelberg)

f. *WE* is responsible for a tremendous ever-growing body of essential scholarship. New directions apart, special issues and symposia have focused on particular themes and area studies. Given its extensive network of senior young scholars, and the authority it commands, we can be certain that field, interest, direction and dynamics are secure and flourishing. *WE* as a whole is far greater than the sum of its parts. (Edwin Thumboo, National University of Singapore, Singapore)

g. The essential and unique value of *World Englishes* over the past 20 years has been to give legitimate status to uses of English that do not conform to Inner Circle norms, and to represent them not as derived varieties but as independent versions of the language in their own right. This is a major achievement and it has given momentum to the gradual recognition that English can no longer be claimed as the property of its native speakers but belongs to all those who have appropriated it for their own social and communicative purposes. (Henry Widdowson, University of Vienna, Austria)

h. Looking back over 20 years of its influence on academia and societies world over, the journal is destined to continue to grow like wine—improving every year. Congratulations, and viva *World Englishes*. (Yasukata Yano, Waseda University, Tokyo, Japan)

Intelligibility, World Englishes, and the Smith Paradigm

A concerned observer of the English language who raised pragmatic questions about the much-debated issue of “intelligibility” did so on the basis of his research in all three circles of Englishes. This was Larry Smith with his team at the East-West Center in Hawaii. In his paper presented in Nagoya (2003), Smith explained: “World Englishes by definition exhibits variation, therefore, it is natural that intelligibility becomes an issue for those using world Englishes across cultures” (Smith, 2003, p. 52). Smith provided a contextually appropriate construct for explaining “intelligibility” in World Englishes. In his paper, he discussed definition of intelligibility, comprehensibility, and interpretability; intelligibility versus comprehensibility; comprehensibility versus interpretability; intelligibility and comprehensibility versus interpretability, and their relation to fluency and cultural competency.

These were pragmatic questions not discussed before in the teaching of English in Asia, Africa and other parts of the world. It was taken for granted that the model for teaching English was in the hands of the colonizers. Studies by Smith and others provide yet more empirical evidence to open doors for new conceptualizations of World Englishes (Smith & Rafiqzad, 1979; Smith & Bisazza, 1982; Sridhar & Sridhar, 1992; Smith, 2003; Smith & Nelson, 2006; Smith, 2009).

In the ongoing and never-ending debate about the issue of intelligibility and its constructs, Smith (2009) comments:

Although we may never be able to totally understand another person's feelings or perspectives in cross-cultural situations . . . we can attempt to increase our likelihood of understanding or at least decrease the possibility of misunderstanding by developing a greater awareness of three of the dimensions of understanding (intelligibility, comprehensibility and interpretability). (p. 17)

In 1985, in the first issue of *World Englishes*, C. L. Nelson provided additional data to Smith's research with the title, "My language, your culture: Whose communicative competence?" A more detailed and updated version was published later (Smith, 1992).

Nelson has designed his 2011 publication on intelligibility from a pedagogical perspective. As Smith so aptly remarks about Nelson's book: "It is highly instructive to have the question of intelligibility across the Three Circles be constructed not only in terms of traditional pedagogical norms and economic advantages, but also taking into consideration linguistic ecology, international pragmatics and sociocultural realities" (Nelson, 2011, p. ix). The book focuses on the following topics: "understanding" and intelligibility in World Englishes; intelligibility, comprehensibility, interpretability; hybridity, creativity, and intelligibility in World Englishes; intelligibility in English-language teaching; and intelligibility and the ongoing expansion of Englishes.

World Englishes: Questions and Answers

The following questions were asked by Jacqueline Kam-mei Lam, chief editor of *The Hong Kong Linguist*, in an interview with B. B. Kachru (Lam & Kachru, 1999). They are very appropriate and relevant even a decade later.

JKL: *When did you first begin to use the term "world Englishes"? Had anyone else used the term at that time, or were you the first?*

BBK: The use of the term actually goes back to the 1970s. I had been using the term "world Englishes" in my seminar at Illinois before it was proposed to Pergamon Press, Oxford as the title for a reincarnated journal when they invited Larry Smith and me to "re-launch" *World Language English*. In 1985, *World Englishes: The Journal of English as an International and Intranational Language* was launched. The term "World English," without pluralization, had been used in some contexts earlier. The reincarnated journal, as Tom McArthur says, "has been a vehicle for the discussion, both general and specific, of varieties of English worldwide, and has in the process firmly underlined the neologism *Englishes* in linguistic and educational circles. The journal's editorial stance is that all 'world Englishes' (native and non-native) belong equally to all who use them and merit serious and consistent study both individually and collectively" (1998, p. 61).

One might say that world Englishes (WE) captures several demographic and contextual characteristics of the cross-cultural profile of the English language. The following come to mind: the functional range and the depth of penetration of the language in various levels of society; the resultant localized innovations and creativity in the language; the multi-cultural and literary identities of the language and its multiple canonicity; and indeed the agony and ecstasy about the global presence of the language.

In the use of this term, the emphasis, then, is on the "WE-ness" that is associated with the medium and its multiple messages or mantras. This conceptualization of English . . . naturally rejects the perpetuated dichotomy between "us" and "them"—between "native" and "non-native." As we know, it is this dichotomy that the "ELT (English Language

Teaching) Empire”—to use the Australian lexicographer Susan Butler’s term—has cultivated and nurtured. It is again this dichotomy that underlies the on-going culture wars about the language . . . We must emphasize that this “WE-ness” is embodied in various strands of Englishes across cultures and languages: their reaches and ranges of uses are unparalleled.

The English language is used in Asia and Africa as a medium to articulate various types of cultural emblems and also as a sociopolitical linguistic weapon. I have often mentioned in my writings the insightful and refreshing ways in which Nigeria’s Wole Soyinka, India’s Raja Rao, the Philippines’ F. Sionil Jose, and Singapore’s Edwin Thumboo use the English language to represent their distinct cultural identities—in other words, to use the medium as an emblem. Soyinka believes that his people “carved new concepts in the flesh of white supremacy” by the “conversion of the slaving medium into an insurgent weapon” (Soyinka, 1993, p. 88). India’s Vivekananda (1863–1902) used the same linguistic weapon—both in his multilingual country and the West—for conveying the message of Vedanta and for setting up the Ramakrishna Mission for spiritual and social awakening. Vivekananda’s pragmatic mind crossed the stifling linguistic boundaries and argued that “the British Empire has given us a machine and I will put the ancient truths of Vedanta in it, broadcast them to the world and make them run like a fire.” The Indian monk used the medium with elegance and success across the Western world. It is all these worlds the medium represents—the Asian world, the African world, and indeed, the Western world. This is, therefore, not a minor achievement, and I believe that we should celebrate it, and participate in using the medium for articulating our visions. We at last have a medium that to a large extent realizes the dream of a “universal language.” What we need, then, is to reevaluate our traditional conceptualizations—theoretical, methodological, and pedagogical—about the current functions of English in a variety of global contexts. That, of course, is happening, but with resistance because all types of interests are involved. And we should not underestimate the economic interests that determine the debate about whose standard, whose model, and whose pedagogical materials are to be used world-wide. (See also Tam, 2004)

JKL: *As a journal editor I must also ask you about your journal “World Englishes.” Has it developed as you expected, or has it taken on a life of its own that sometimes surprises you?*

BBK: Well, the way the journal *World Englishes* has evolved has not exactly surprised us. Larry Smith and I had realized that there was actually a space for a professional journal to represent the sociolinguistic, cultural, political, and economic realities about the global presence of the English language—I mean all the dimensions of it, the linguistic and literary issues and also the agonies and ecstasies. The senior and aspiring researchers and educators in English studies received the journal with contagious excitement, especially in Africa, Asia and other regions where English is an additional language. These were voices whose creativity in the language and identity with it in varied cultural contexts had hardly any international scholarly resource for expression or discussion. We believe that *WE* provided that scholarly resource.

. . . *WE* has a unique character and represents multiple voices—and we have sustained that multidisciplinary representation and international presence, African, Asian, European, North American, and so on, during the past fifteen years.

I don’t think I can say it better than Tom McArthur did (1993, p. 334) referring to the logo-acronym of the journal. He observed that the logo “serves to indicate that there is a club of equals here.” In McArthur’s interpretation of the logo, he rightly emphasizes that the emphasis is on “the democratization of attitudes to English everywhere on the globe.” This interpretation, as McArthur adds, also dissolves the trinity of ENL, ESL, and EFL nations. I think the concept “world Englishes” certainly represents that fact about the current status and functions of global English. (See also Boyle, 2004)

Resources for the Study of World Englishes

The history of World Englishes and its constructs has been discussed not only in the English language but also in languages such as Chinese, German, Japanese, and Russian. A list of major studies in English for research on World Englishes includes the following: Bamgboṣe, Banjo, and Thomas (1995), Smith and Forman (1997), Boyle (2004), Tam (2004), Kachru (2005), Bolton and Kachru (2006a, 2006b), Y. Kachru and Nelson (2006), Bautista and Bolton (2008), and Kachru, Kachru, and Nelson (2006), Kachru and Smith (2008).

Holliday, Adrian

TREVOR GRIMSHAW

Best described as a sociologist of applied linguistics, Adrian Holliday (1950–) has made substantial contributions to our understanding of how international language education influences the (inter-)cultural realities of individuals within diverse settings.

Holliday began his academic career with a BSc in sociology and a Postgraduate Certificate in Education specializing in social science. This background continues to inform his work. After a year teaching in a British state secondary school, he spent most of the 1970s working on British Council ESP curriculum development projects in Iran. He obtained his MA from Lancaster University in 1980. As a British Council curriculum adviser he established the ESP language center in Damascus University (Syria), then worked on a national preservice language teacher education project based at Ain Shams University, Cairo (Egypt). He completed his PhD at Lancaster University in 1991 under the supervision of Dick Allwright and Michael Breen. Based on his experience in Egypt, his thesis examined the relationship between local and expatriate project personnel.

Since 1991 Holliday has been based at Canterbury Christ Church University, where he is currently professor of applied linguistics and head of the graduate school. In the 1990s he played a leading role in BATQI (the British Association of TESOL Qualifying Institutions), contributing to the design of the first common framework of accreditation for TESOL certificate, diploma, and masters programs. He acknowledges that he has learned a lot from the work of his doctoral research students.

Holliday's early research referenced classic social theorists, including Schutz (1967), Bernstein (1971), and C. Wright Mills (2000). In more recent work he has drawn upon postmodern and postcolonial theory. Social action theory has served as a constant frame of reference throughout.

Holliday challenges the essentialist view of culture and language that prevails within popular discourse and the positivist paradigm of social science. This views cultures as homogeneous and mutually exclusive entities that are associated with a particular country and language. Holliday argues that this perspective leads to negative cultural stereotyping and ethnocentrism. In contrast, he views cultures as discursive constructs that must be discovered in process. These can exist on any scale, for example, an international association of TESOL practitioners or an informal order within a university department. Holliday proposes the notion of "small cultures" which can serve "as an interpretive device for understanding emergent behavior, rather than seeking to explain prescribed ethnic, national or international difference" (1999, p. 237). Holliday's "host culture complex" (1994, p. 29) sees the language classroom as one of numerous overlapping and interacting cultures, where local discourses may at times exert greater influence than national or international ones.

Holliday's research is characterized by a critical qualitative approach, involving the ethnographic techniques of thick description and bracketing. He describes this methodology in a handbook for novice social science researchers (2007).

Holliday has applied a sociological imagination to many of the key issues and concepts associated with the TESOL profession of the Anglophone West: language needs analysis, authenticity of materials and tasks, communicative classroom practices, learner-centeredness,

learner autonomy, and the management and evaluation of language teacher education programs.

A leading figure in the “appropriate methodology” movement, Holliday published the first book on this topic (1994). Developing ideas from his doctoral research, he uses the metaphor of “tissue rejection” to explain cases where expatriate “Western” curriculum developers attempt unsuccessfully to graft incompatible innovations onto an unreceptive host academic culture. To achieve cultural continuity, Holliday proposes the ecologically sensitive method of “ethnographic means analysis” (1994). His aim is to develop hybridized forms of pedagogy that combine communicative language teaching with features of the local culture.

In more recent work Holliday has explored the politics of Self and Other within the context of international English language education and the broader field of intercultural communication. He has popularized the term “native-speakerism,” which describes the cultural chauvinist ideology implicit in the promotion of TESOL methodologies generated by the Anglophone West (2005). This leads Western trained educators to construct their non-native students and counterparts as deficient (“passive,” “uncritical,” “rote learning,” “teacher dependent,” etc.) and compels them to seek (often unwittingly) to “correct” these imagined deficiencies.

However, Holliday rejects the simplistic dichotomization of “center” and “periphery” that characterizes Phillipson’s (1992) linguistic imperialism thesis, seeing this as the perpetuation of an “otherizing culturist discourse” (Holliday, 1997, p. 415). He also challenges Jenkins’s (2000) notion of a standardized English as a lingua franca (ELF) as an antidote to the marginalization of the “non-native-English speaker” (Holliday, 2008). He argues that, in order for the TESOL profession to develop, it must overcome false dichotomies and become more inclusive. For this same reason, Holliday has in recent years sought to distance himself from the acronyms BANA and TESEP, which in earlier publications (e.g., 1994) he himself had suggested for describing distinct professional-academic cultures of TESOL (British, North American, Australasian, private sector vs. “*T*ertiary, *S*Econdary and *P*rimary” state sector).

A handbook on intercultural communication (Holliday, Hyde, & Kullman, 2010), coauthored with Canterbury colleagues, suggests a range of non-essentialist strategies that could be employed by readers within the fields of communication studies, linguistics, and sociology. The book argues that “all communication is intercultural” (2010, p. xv), since identity construction, otherization, and representation occur in all areas of society.

Holliday (2011) takes a “critical cosmopolitanist approach” in exploring how cultural chauvinism operates within a context of unequal global power relations. The tendency of academic and professional communities to seek conceptual certainty encourages reductionist notions such as the dichotomy of individualism/collectivism. These neo-essentialist ideological constructs may lead us to assume that cultural differences are insuperable. However, Holliday insists upon individual agency, emphasizing the fact that interpretations of culture are derived from personal circumstances.

Holliday’s theoretical stance has evolved over time. His self-reflexive methodology has helped him to stand outside prevailing discourses and to develop a progressively more nuanced understanding of the processes of cultural interaction. In sharing his conceptual breakthroughs with the reader, he offers a model to new and more experienced researchers. His work helps us to appreciate the interdisciplinary nature of applied linguistics and the valuable contributions it can make to other fields.

Hornberger, Nancy H.

FRANCIS M. HULT AND DAVID CASSELS JOHNSON

Nancy Hughes Hornberger (b. 1951) is an internationally recognized scholar in language planning and policy, bilingual education, and biliteracy. Her work emphasizes relationships between policy and practice in multilingual education, with an emphasis on equity and justice for immigrant minorities and indigenous peoples. Peru and Bolivia have been central foci for field research during her career, though she has consulted and conducted research throughout the world.

Professional History

Her interest in languages and bilingualism began while she was growing up in California. Her fifth grade teacher, having just been introduced to the audio-lingual method, began teaching Spanish as an elective, and her parents encouraged her to participate. Later, as a teenager, she was an exchange student in Brazil, which sparked an interest in the Portuguese language as well as Latin American studies.

Hornberger continued to pursue her interests at Harvard University, where she earned a bachelor's degree in Hispanic-American History and Literature in 1972. Immediately after completing her undergraduate studies, Hornberger, inspired by programs blossoming in Massachusetts and New York following the 1968 passage of the Bilingual Education Act, decided to pursue graduate studies in bilingual education at New York University, earning a master of arts degree in education in 1973. She soon had another opportunity to pursue her interest in Latin America.

She and her husband, Stephan Hornberger, whom she met at Harvard, were approved by the Lutheran Board of Missions to do missionary work in the Andes. They worked in Peru from 1974 through 1979. During the first six months, they studied Quechua at the Instituto de Idiomas, an ecumenical missionary training center administered by the Maryknoll Fathers and Brothers, in Cochabamba, Bolivia. Here they received intensive language training from native-Quechua-speaking instructors, which included daily four-hour classes in the mornings followed by audio-lingual training with cassette tapes in the afternoons. They were, at the time, also living with a Quechua-speaking family, which afforded them the opportunity to use Quechua for daily interactions.

Studying Quechua in Cochabamba led to a major scholarly contribution. In order to learn new words in Quechua, they created an extensive set of vocabulary cards. The instructors were impressed with the cards and encouraged the Hornbergers to publish them as a resource that other students of Quechua could use. By 1977, they had expanded upon these cards to create the *Trilingual Dictionary: Quechua of Cusco, Spanish, English* (Hornberger & Hornberger, 1977). The dictionary would be revised twice, with the third edition heavily changed to reflect the official Peruvian alphabet (Hornberger & Hornberger, 1983, 2008; see Hornberger, 1995a). This dictionary, which emerged directly from language teaching and learning, exemplifies the relationship between research and practice that continues to be the hallmark of Hornberger's work.

After five years in Peru, recognizing that additional graduate study was necessary in order to engage in more advanced development work, Hornberger decided to pursue

doctoral studies. She was accepted to the program in Educational Policy Studies at the University of Wisconsin-Madison in January 1980. At Madison, she worked under Richard Ruiz, along with a small group of other doctoral students who were also interested in language and policy. In the summer of 1980, Hornberger won a scholarship to attend the Linguistic Society of America (LSA) Institute at the University of New Mexico. It was here that she first encountered Joshua Fishman, whose work would come to influence her dissertation research as well as other work throughout her career. At the LSA Institute, she also studied with Peruvian sociolinguist Rodolfo Cerrón Palomino and educational linguist Courtney Cazden.

In January 1982, Hornberger returned to Peru, with her family, to conduct dissertation research. She worked in the highland communities of Kinsachata and Visallani. Her study (Hornberger, 1985, 1988), which compared beliefs about language and language use across classrooms and communities in light of developments in bilingual education policy, was groundbreaking in its integration of principles and methods from ethnography, sociology of language, and language planning. She earned a PhD in educational policy studies with a minor in linguistics from the University of Wisconsin-Madison in May 1985.

Soon after completing doctoral work in Madison, Hornberger was hired as an assistant professor at the University of Pennsylvania Graduate School of Education, where Dell Hymes had been appointed dean. A major focus of Hymes's vision as dean was to advance the linguistic anthropology of education, which included establishing a doctoral program in educational linguistics (Hornberger, 2001a, 2009a). Hornberger's work, with its intersecting focus on education, bilingualism, and policy, matched well with Penn's program, and she joined the faculty of the Language in Education Division in the fall of 1985. As a junior faculty member, she would sit in on Hymes's courses on linguistic ethnography, gaining new insights that would continue to shape her own view of educational research (Hornberger, 1995b). Later, as a senior faculty member, Hornberger was appointed director of the doctoral program in educational linguistics, a position she continues to hold. Over the 25 years that she has been on the faculty at Penn, Hornberger has supervised over 40 doctoral dissertations, written over 100 articles and chapters, and authored or (co-)edited 30 books and volumes. Her work has contributed to shaping the field of educational linguistics and inspired scholars throughout the world.

Major Contributions

Hornberger's first flagship publication was her book-length monograph, *Bilingual Education and Language Maintenance*, published in 1988, the written result of 15 years spent living in highland Peru and working with Quechuas and Quechua language education. She describes the central concern of this seminal ethnographic work as follows:

I am concerned with how best to use and teach languages in schools, and with the possibilities for including minority groups in schools through use of their language, and in society through their participation in schooling. These concerns, in turn, are shaped by my own assumptions about language, education, and social justice, namely that: multiple languages and cultures are inherently valuable for society, that all groups in society have a right to participate equally in that society, and that education must be available to all. (Hornberger, 1988, p. xv)

This, from the preface to her 1988 monograph, reveals what would become major themes in her work: (a) the macro-micro connection in language policy and education; (b) the importance of (bilingual) education in maintaining and validating indigenous and minority languages; and (c) a commitment to social justice and activism for minority and indigenous

peoples and languages. Out of these initial concerns, another important theme has emerged throughout the years: (d) a comparative streak engendered by Hornberger's advocacy for different languages and peoples around the world.

The breadth and depth of Hornberger's research, and her formidable record of publications, have led to many important theoretical and empirical contributions that continue to lead and inspire. She has been a forerunner in combining macro- and micro-sociolinguistic research methods and her work is decidedly interdisciplinary, yet grounded in the field of educational linguistics (Hornberger, 2001a). She has led the way in using ethnography to establish connections between macro-level language planning and policy and micro-level language policy, practice, and education in multiple contexts including South America, especially Andean countries and languages (Hornberger, 1987a, 1987b, 1988, 1998, 2000; Hornberger & King, 1996), and the United States, with particular attention to Puerto Rican and Cambodian communities in Philadelphia (1990, 1996, 1997a; Hornberger & Micheau, 1993; Hornberger & Hardman, 1994; Hornberger & Skilton-Sylvester, 2000).

As the field of language planning and policy (LPP) has become increasingly more critical, with the focus being on how policies are instruments of power that marginalize cultural and linguistic minorities, Hornberger has continued to offer a more complex yet evidence-based perspective of the multiple agents and contextual layers that potentially have power in LPP, and she has been a persistent advocate for the power of bottom-up agency (Hornberger, 1997b, 2005, 2009b; Ricento & Hornberger, 1996; Hornberger & Johnson, 2007). She discussed, in more detail, important findings from this line of work in her 2008 plenary address to the American Association for Applied Linguistics when receiving the Distinguished Scholarship and Service Award (Hornberger, 2008b), which, in turn, was translated into an article for *Language Teaching* (Hornberger, 2009b).

To summarize her vision of policy and practice: (a) Language policies *can* marginalize minority language use and users, but language policies can also create space for multilingualism, and multilingual language policies have opened spaces for bilingual education throughout the world (e.g., Hornberger & López, 1998; Hornberger, 2006b). (b) Language in education policy is a tool to preserve indigenous and minority languages. Bilingual education, and especially maintenance or developmental bilingual education (Hornberger, 1991), has become a powerful ally in the maintenance and revitalization of indigenous and minority languages (Hornberger, 1997a, 2006a, 2009b; Hornberger & Johnson, 2007). (c) Still, top-down language policies may not necessarily be enough since "any policy may fail if there is no bottom-up support" (Hornberger, 2009b, p. 199). This has become an accepted tenet in the field of LPP, in part because of Hornberger's work in Peru showing that national multilingual policies that promoted Quechua did not necessarily translate into classroom practice (Hornberger, 1987b, 1988). (d) Schools are not always enough, either. Even though schools and educators play a powerful role in the maintenance of indigenous and minority languages, like national language policies, schools, as well, may not be enough (see also Fishman, 1991). For example, Hornberger and King (1996) argue that the instruction and use of indigenous tongues in schools extends their use, and increases their status, yet the schools' linguistic impact may be limited and the "responsibility of reversing the language must not be left solely upon the shoulders of the school . . . such school-based initiatives crucially rely on surrounding and supporting community initiatives" (Hornberger & King, 1996, p. 439).

Along with these important findings on language planning, policy, and education, Hornberger has made numerous theoretical and conceptual contributions and proposed robust frameworks and heuristics that continue to guide a new generation of researchers. The conceptual framework for bilingual education models (Hornberger, 1991) made great strides in teasing out the multiple (often conflicting and confusing) definitions and descriptions of different bilingual program types. Her continua of biliteracy (Hornberger, 1989,

2002, 2003, 2004; Hornberger & Skilton-Sylvester, 2000) is a robust, comprehensive, yet flexible model to guide the use, learning, and teaching of two or more languages in and around writing. Her Integrative Framework for Language Policy and Planning Goals combines three decades of scholarship into an incredibly useful guide to the approaches, types, and goals of language policy and planning (Hornberger, 1994, 2006b). As well, Hornberger has made important strides in incorporating the ecology of language as both metaphor and paradigm in LPP, examining how languages and policies are situated in relation to each other within particular linguistic environments (Hornberger, 2002; Hornberger & Hult, 2008).

Hornberger does not tend to refer to herself as an activist but her concern with social justice is clear and both her research on bilingual education policy and practice and her advocacy for a multilingual ecology have inspired researchers and educators throughout the world. Beginning in the 1990s, Hornberger has tirelessly trekked across the globe to consult on language policy and education matters, advocating for bilingual policies and practices all along the way, and building collaborative working relationships with other scholars and educators. This work has been a foundation for comparative analyses across multiple contexts including Bolivia, Peru, Paraguay, Ecuador, Brazil, Wales, the USA, India, South Africa, New Zealand, Sweden, and Singapore, which affect multiple languages including (among others) Spanish, Quechua, Māori, Guarani, Khmer, Shawandawa (i.e., Arara), Afrikaans, Sepedi, English, Sámi, Singlish, Zulu, and Xhosa (see Hornberger, 1997a, 1998, 2000, 2001b, 2002, 2008a; Hornberger & Chick, 2001; Hornberger & Johnson, 2007; Hornberger & Hult, 2008; Hornberger & Vaish, 2009).

This work, in and of itself, has opened spaces for bilingual education policy and practice within particular contexts but the comparative streak in her published work has also illuminated the *connections between* different contexts and thus Hornberger has helped create a worldwide network of educators and scholars whose efforts contribute to a global project aimed at protecting and supporting minority languages and peoples (e.g., Hornberger, 2008a). One such partnership, begun in the late 1990s, is her ongoing collaboration with the South African scholars Neville Alexander and Carol Bloch and their work on the Project for the Study of Alternative Education in South Africa (PRAESA), which promotes the use of minority African languages as mediums of instruction in African schools. Bloch describes Hornberger as an “inspiration and a support for our work in South Africa.” Not only has her continua of biliteracy been used as a framework for biliteracy education in schools, but her advocacy for African languages and bilingual education and her position as a well-respected researcher has benefited their efforts in multilingual policy and practice: “Sometimes, when you are working deep in a particular context where the need is so great, the problems so huge, and the opposition so vociferous and unacknowledging, it helps enormously to have support from authoritative ‘outside’ voices” (C. Bloch, personal communication, 2010). As a result of this collaboration, Hornberger has written extensively about language education policy in South Africa and the burgeoning multilingual population in South African schools, engendered by the dismantling of the apartheid educational system and a new constitution of 1993/1996 which embraced multilingualism as a national resource (Hornberger, 1998, 2001b; Hornberger & Chick, 2001; Hornberger & Vaish, 2009).

The praise of her colleagues, the extensive list of publications, the advocacy work throughout the world, and the inspirational and essential contributions are all testaments to Nancy H. Hornberger’s impact upon the field thus far; yet, a quick look through the reference list that follows reveals that her publication output in recent years has not slowed in the slightest, evidence that her indomitable ingenuity will continue to prosper and inspire well into the future.

House, Juliane

SHOSHANA BLUM-KULKA

Juliane House is emerita professor of Applied Linguistics and senior member of the German Science Foundation's Research Center on Multilingualism. She has been a leading figure in applied linguistics for several decades, making significant contributions to several areas including translation, intercultural communication, cross-cultural pragmatics, and discourse analysis, and more recently to the understanding of the role of English as lingua franca. She was amongst the first scholars who understood early on the relevance of pragmatic theory for applied linguistics, and has widely demonstrated its significance for theoretical issues in translation quality assessment, intercultural communication, and second language learning and teaching.

Juliane House was educated at German and Canadian universities. She obtained a diploma in English, Spanish, and international law from the University of Heidelberg in Germany, and continued her undergraduate and graduate studies at the University of Toronto, specializing in linguistics and applied linguistics. On her return to Germany she served as a lecturer and researcher for five years at the University of Bochum (1974–9) and was subsequently (1979) appointed Professor of Applied Linguistics at Hamburg University, where she remains to date. She has been involved in several large-scale innovative research projects in contrastive studies of English and German, native and non-native communication, speech act realization patterns, translation and global English, and has published widely in both German and English.

Juliane House's pioneering PhD dissertation, "A Model for Translation Quality Assessment," laid the ground for the introduction of pragmatic models of language use to translation studies. This seminal work, first published in 1977, has been revised and republished several times, most recently in 2009, and continues to be highly influential. The model originally drew on pragmatics, Hallidayan linguistics, and discourse analysis, and was later enriched by taking into account the interdependency of language, culture, and situation (House, 2009). House's ongoing work on translation assessment is richly informed by her detailed contrastive discourse analyses of German and English. This line of work has revealed important cross-cultural differences in the pragmatic systems of the two languages, as manifested in the use of gambits, opening phases in conversation, topic introduction, speech act realization patterns, and discourse strategies (House, 2006).

House's extensive contrastive-pragmatic work is further linked to issues of language learning and cross-cultural misunderstanding(s). In a theoretically and methodologically innovative large-scale project, she and her colleagues (with Edmondson, Kasper, and Stemmer, 1976–81) pursued the learning of the pragmatics of discourse via analyses of role-played native–non-native and native–native interactions. This project provided an empirical and pedagogical basis for the then relatively new communicative approach to language teaching by highlighting crosslinguistic differences in language use between German and English, by revealing German L2 interlanguage pragmatic phenomena, and by providing an interactional grammar of German for its teaching communicatively as L2 (House & Edmondson, 1981; Edmondson, House, Kasper, & Stemmer, 1984). This project can be counted among the very first studies of L2 pragmatics.

Cultural differences in ways of speaking can also lead to misunderstandings. One of House's important contributions to intercultural communication was in showing the impact

of such cultural differences in communicative styles by speakers of different languages on intercultural misunderstandings, demonstrating the role played by such differences for culture clashes and for the perception of misunderstanding and (im)politeness (House, 2000, 2007; House, Kasper, & Ross, 2003).

Cross-cultural differences in pragmatic systems were also the focus of the Cross Cultural Speech Act Realization Project (CCSARP), headed by Blum-Kulka, House, and Kasper. The study integrated linguistics, speech act theory, and politeness theory in demonstrating cross-cultural and situational variation in the performance of requests and apologies (Blum-Kulka, House, & Kasper, 1989). This study laid the foundations for the empirical study of speech acts in different languages, developing a theoretically motivated methodological framework for the analysis of speech acts realization patterns across cultures. One of the important contributions of the study was in showing that cross-cultural variability in speech act realization patterns is a gradient phenomenon—all languages studied made use of the full repertoire of a given speech act, but they did so with great contextual (within-language) and cultural (across languages) variability.

More recently, House has become, on the basis of her multifaceted research on English as a lingua franca (ELF), a strong advocate for the need to consider ELF as a hybrid, functionally flexible, and open-ended language of communication, rather than as a threat to national languages and multilingualism. One part of her argument is based on findings from studies considering the impact of English on central genres in other languages. She has shown, in her comparative studies on translation and parallel texts in pairs of two languages, that contrary to initial expectations, and despite the wide use of English in the second half of the 20th century, signs of Anglicization in terms of discourse norms remain scarce over a period of 30 years. Thus translations were shown to go through a “cultural filter,” adapting the texts to major target language discourse norms like preference for “content orientation” (in German) versus “addressee orientation” (English) (Becher, House, & Kranch, 2009). A further step in the argument considers the effectiveness of non-native–non-native ELF communication; her studies have shown that despite the presence of native ways of speaking that filter through to ELF in such interactions, participants manage to communicate effectively, with very few misunderstandings (House, 2003, 2010).

To conclude, Juliane House is a versatile and innovative scholar, with a clear voice on many central issues in applied linguistics. The diverse topics she is and has been interested in are motivated by an unfailing quest for understanding the impact of culture on language use, linked by an underlying pragmatic and functional linguistic theoretical outlook, and typified by an ongoing commitment to considering the “applied” implications of her findings—be it for language teaching, translation, or intercultural communication.

Hulstijn, Jan H.

JANNY LEUNG

Jan H. Hulstijn (1947–) is a Dutch scholar whose research is primarily concerned with incidental and intentional second language (L2) vocabulary learning, implicit and explicit L2 grammar learning, automatization of L2 lower-order processing skills, and language proficiency (LP). He postulates that there is a fundamental difference between implicit and explicit learning, although explicit learning incidentally provides opportunities for implicit learning. His joint proposal with Laufer, called the involvement load hypothesis, predicts that vocabulary retention is determined by the depth of processing required by the learning tasks. On a broader theoretical level, he works toward a unified account of L2 acquisition, representation, and processing, arguing that the apparently divergent approaches of symbolism and connectionism may be reconciled in a hybrid model. His theory of LP proposes a distinction between basic language cognition and higher language cognition.

Hulstijn has led many large-scale longitudinal and cross-sectional studies in second language acquisition (SLA) and his works have appeared in international journals such as *Applied Psycholinguistics*, *Language Learning*, *The Modern Language Journal*, *Studies in Second Language Acquisition*, and *Second Language Research*. He has published in English, Dutch, French, and German.

Professional Life

Hulstijn's doctoral thesis, completed with the University of Amsterdam, was titled "Monitor Use by Adult Second Language Learners." After obtaining his doctorate in 1982, Hulstijn worked for one year as a research associate at the Modern Language Centre of the Ontario Institute for Studies in Education in Toronto with a grant from the Netherlands Organization for Scientific Research (NWO). He worked at the University of Leiden and the Vrije Universiteit Amsterdam between 1983 and 1998, and has been professor of second language acquisition at the University of Amsterdam since 1998. He was guest professor at the University of Leuven, Belgium (2002), and Stockholm University (2005) and is a project leader of multiple NWO grants.

Ideas

When compared with research on L2 grammar learning, progress in L2 lexical research has been slow in recent decades, despite the fact that words are central to language. While teachers and researchers have limited control over what people do to intentionally commit new words to memory, incidental vocabulary learning seems to lend itself to controlled empirical investigation. Incidental vocabulary learning refers to the unintentional picking up of unfamiliar words; for instance, it is commonly accepted that people pick up vocabulary during reading tasks.

Hulstijn has made continued efforts in finding out the factors that are conducive to incidental vocabulary learning, especially the ones that affect not only immediate comprehension but longer-term retention. Hulstijn (1992) shows that words whose meanings

were correctly inferred from context during a reading task were subsequently remembered better than words explained by a synonym. Hulstijn, Hollander, and Greidanus (1996) have also found that the vocabulary items that were looked up in the dictionary during a reading task yielded much higher retention scores than the same words in the marginal gloss condition. Looking up words in an L1–L2 dictionary and applying them in a composition also seems to produce better retention than looking up in an L2–L1 dictionary for comprehension purposes (Hulstijn & Trompetter, 1998). The motivation to look up words in a dictionary during reading may be boosted by pre-reading test announcements and post-reading vocabulary tasks (Peters, Hulstijn, Sercu, & Lutjeharms, 2009). Added together, these studies suggest that some tasks are superior to others in terms of incidental vocabulary learning, and the superior tasks tend to be ones that involve greater depth and elaboration of processing.

However, it remains obscure what makes processing deep or elaborate. In collaboration with Laufer, Hulstijn has attempted to operationalize the notions of depth of processing and elaboration in the context of L2 vocabulary learning by proposing the involvement load hypothesis (Laufer & Hulstijn, 2001). *Involvement* is a motivational-cognitive construct that consists of three basic components: *need*, *search*, and *evaluation*. According to the hypothesis, retention of unfamiliar words is dependent upon the degree of involvement in processing these words. In a study involving English as a foreign language (EFL) learners in Israel and the Netherlands, Hulstijn and Laufer (2001) found that retention of incidentally acquired vocabulary is contingent on the amount of task-induced involvement, lending support to their hypothesis.

Apart from involvement load, Hulstijn (Hulstijn & Laufer, 2001; Hulstijn, 2002a) has also emphasized the importance of placing frequency in an overarching theoretical framework of language acquisition. He has pointed out that implicit knowledge, such as that of form–form connections, may be more susceptible to frequency effects than explicit knowledge, such as that of form–meaning connections. Frequency also seems to affect receptive language more than productive language.

While explicit learning may occur incidentally or intentionally, implicit learning may only take place incidentally. Hulstijn believes that research on implicit and explicit learning is of critical value to the study of SLA (Hulstijn, 2005), since such research potentially offers an explanation for the differential success in first language (L1) acquisition and SLA, a central controversy in the study of language acquisition. Hulstijn has argued that L1 acquisition relies principally on incidental and implicit learning mechanisms, and that it would be of obvious pedagogical interest to find out what L2 domains might best benefit from implicit or explicit learning modes.

Hulstijn has changed his view substantially over the years on the interface problem of explicit and implicit learning. He first switched from a strong interface position (1990) to a weak one (1995), according to which explicit grammar instruction facilitates foreign language acquisition. Although later in his career he has moved to a non-interface position (i.e., holding that explicit knowledge cannot be transformed into implicit knowledge; see 2002b and below), his belief that explicit learning somehow (albeit indirectly) facilitates implicit learning still stands. Hulstijn (1995) acknowledges that some L2 learners have no explicit knowledge of grammar rules, but can apply them correctly, while others keep on making errors despite their explicit knowledge of the rules. However, he does not believe that grammar teaching should be eschewed altogether. In fact, since implicit learning may take an extremely long time and extensive input might not be available, and attention to form is required for the acquisition of word order rules (Hulstijn & Hulstijn, 1984), it is advisable to promote explicit learning in an instructional context (Hulstijn, 2002b).

For teachers who are torn between the choice of teaching difficult grammar rules and leaving easy features to be picked up by learners, or teaching simple rules that can be easily comprehended by students, Hulstijn (1995) postulates that explicit teaching and practicing are more useful for some types of grammar rules than others. The five criteria that he considers relevant are scope, reliability, frequency, mode of command, and comprehensibility of explanation.

Not only are humans able to produce complex, structured, and regular utterances, they are also able to learn fuzzy, prototype-like categories. A successful language acquisition theory should therefore incorporate both types of cognition, Hulstijn argues. Noting that both symbolism and connectionism are relevant for SLA, Hulstijn urges for a reconciliation between the two approaches, and for more research on the types of linguistic principles, rules, or elements that may be learned by associations (1997, 2002b, 2003). In an effort to integrate the two accounts from a non-nativist, emergentist perspective, Hulstijn (2002b) propounds that sub-symbolic knowledge may be learned implicitly, and components (most likely lexical units) of the distributed knowledge network might elevate to the status equivalent of “symbols,” while symbolic rules may be constructed via explicit learning. He also speculates that lower linguistic domains (such as acoustic perception) are more likely to take the form of sub-symbolic representations and higher domains (such as pragmatics) might consist of more symbolic representations. Although explicit knowledge cannot be converted into implicit knowledge, explicit learning might create opportunities for implicit learning, since the latter is an unstoppable information processing mechanism that automatically accompanies any explicit learning activity. His influential view is at odds with perspectives that call for research efforts in ensuring “pure” explicit or implicit learning conditions (e.g., DeKeyser, 2003).

At the methodological level, Hulstijn (1997) has made the following recommendations for laboratory-type SLA research: (a) Experimental treatments to subjects should be of sufficient length; (b) a construct should be measured with more than one task or under more than one task condition; (c) caution should be exercised when measuring reaction times of responses given by non-native speakers; and (d) retrospective interviews or questionnaires should be used at the end of an experiment.

Although Hulstijn sees a valuable role for explicit instruction on the educational agenda, he argues that automaticity of lower-order information processing, which is achieved through implicit learning, is a prerequisite for L2 proficiency, and suggests that SLA researchers should be encouraged to investigate the extent to which SLA is a gradual process or skill acquisition (1997).

Hulstijn cites L1 and L2 acquisition as prime examples of skill acquisition, which typically proceeds slowly and gradually and leads to automatization (Hulstijn, Van Gelderen, & Schoonen, 2009). In line with the non-interface position, he argues that automatization is done through implicit learning and neural network construction which is incidental to explicit learning, rather than through the actual automatization of rules (2002b). Skilled behavior is effortless and is faster than rule application. In his latest language ability theory, Hulstijn (2011a, 2011b) proposes a distinction between basic and higher language cognition, and a distinction between core and peripheral components of LP, which the author contends will help explain individual differences in language achievement.

Human Rights

HUGH STARKEY

Human rights provide a way of looking at the world. Since the publication of the Universal Declaration of Human Rights (UDHR; United Nations General Assembly, 1948), all human beings have potential access to a shared language to describe and name ways in which human dignity may be violated and can be protected. This is facilitated by the existence of 375 different language versions of the Declaration, demonstrating a commitment by the United Nations (UN) to communicating directly with people irrespective of the official status of their language.

Naming something as a human rights issue carries considerable moral weight since all nation-states are in principle committed to upholding human rights. It follows that such naming should be undertaken with caution. However, if a claim can reasonably be established that something is a human rights abuse, the moral case may give political leverage, including the possibility of solidarity from others around the world. It may also be possible in some circumstances to seek legal redress. This entry provides some background information on human rights; it reviews a number of issues where language may be a significant issue in struggles for dignity and human rights; and concludes with some reflections on the contested concept of linguistic human rights.

Defining Human Rights

It has been argued that the development of human rights occurred because human beings felt the need, in the light of human vulnerability, for agreement on moral, political, and legal principles that might protect individuals (Turner, 1993). The principles are abstract and can thus be applied to any context and in any political system. They recognize that human beings live in society and depend on others for their survival and well-being. These standards provide a common point of reference for officials, teachers, and individuals living as members of societies that, with globalization, are composed of people from a wide diversity of cultural, ethnic, religious, and linguistic backgrounds. Human rights are only meaningful when known and understood. However, they are not simply normative standards for encouraging pro-social behavior, but also a set of principles for critically engaging with social and political realities. In other words human rights are essentially associated with struggle (Osler & Starkey, 2010).

Human rights are often spoken of from a historical perspective as having developed in three generations or waves (Klug, 2000). Although human rights are indivisible, this metaphor can remind us of historic struggles (Bowring, 2008). First-wave rights are those civil and political rights necessary for meaningful citizenship. They are associated with the Enlightenment and with struggles for freedom from the arbitrary and unjust actions of colonial powers and of monarchs claiming the divine right to rule. Exemplary historic declarations, asserting equality of rights and the right of subjects to rebel against tyranny, are the United States Declaration of Independence (1776) and the French revolutionary Declaration of the Rights of Man and of the Citizen (1789). Some phrases and formulations drawn directly from these declarations are recognizable in the 20th-century declarations and covenants.

2 HUMAN RIGHTS

The second wave of human rights is associated with social and economic rights. These rights are included in the UDHR and they have their origins in trade-union struggles from the 19th century. Third-wave rights are sometimes called solidarity rights. They are associated with major struggles of the post–World War II period: decolonization; development; peace; and environmental protection. Solidarity rights bring together rights from the previous waves.

The metaphor of generations or waves of rights tends to emphasize the difference between groups of rights rather than their interdependence and indivisibility. One of the key drafters of the UDHR, René Cassin, proposed an alternative model that presents four groups of rights as pillars, holding up an edifice of internationally agreed human rights. Each pillar helps support the edifice of the UDHR, imagined as a classical Greek portico, and each bears equal weight (Cassin, 1951).

The foundations of the portico are the preamble and the first article, a statement of belief in what has developed as natural rights theory, namely that “all human beings are born free and equal in dignity and rights.” This is followed by a normative statement of how people should behave toward each other. “They are endowed with reason and conscience and should act towards one another in a spirit of brotherhood.” The formulation consciously echoes the American and French declarations from the 18th century.

The pillars of the UDHR portico symbolize four key concepts, namely dignity, liberty, equality, and solidarity, the last three recognizable as the motto of the French Republic. Cassin clusters the articles as: personal rights; rights in civil society; public freedoms and political rights; and economic, social, and cultural rights. The pediment capping the edifice represents an international order essential for the realization of rights; understanding that rights imply duties to the community; and a recognition that freedoms do not extend to those actions that jeopardize the rights of others.

The UDHR introduced a new concept of universality. Previous struggles established citizenship rights guaranteed at national level. The essence of human rights, as expressed in the UDHR, is that they are universal and not the gifts of national governments. This great conceptual innovation introduced in the UDHR was theorized by Cassin, based on his experiences representing displaced World War I veterans in Europe (Winter, 2006). Veterans were being denied their rights because they did not hold formal citizenship status. Yet they were clearly members of the communities where they lived. Cassin argued that domicile as well as citizenship should be a source of rights. In other words, rights attach to individuals, wherever they live—they are not the gift of the nation-state. Once rights are conceived as belonging to the individual as human being rather than as citizen of a nation-state, the concept of human rights is possible.

The UDHR was a performative act by the world’s nations. It supported a vision of peace based on democracy and the rule of law and set a moral standard. However, declarations cannot in themselves protect vulnerable human beings; laws are also needed to enforce the standards and ensure that state institutions respect human dignity and fundamental freedoms. There are now some 200 human rights instruments, including declarations, resolutions, guidelines, conventions, and covenants that make up a body of international human rights law (Morsink, 1999). Human rights are universal principles at a high level of generality. They are thus distinct from many other forms of rights such as civil rights or citizenship rights, which depend on membership of a particular nation-state. Human rights can be invoked in struggles for equality, fundamental freedoms, fair treatment, and due process. Human rights claims refer to internationally recognized instruments. It is not legitimate to invoke human rights in order to limit the rights and freedoms of others, nor to undermine the principles of the United Nations (UDHR, Article 29).

The centerpiece of international human rights law is the International Bill of Human Rights. This is made up of the International Covenant on Civil and Political Rights (ICCPR;

United Nations, 1966a) and the International Covenant on Economic, Social and Cultural Rights (ICESCR; United Nations, 1966b), together with the UDHR. The Convention on the Rights of the Child (CRC; United Nations, 1989) is the most ratified of the instruments of the United Nations. Its acceptance in principle and in law by all the world's governments is a demonstration of the universality of a discourse of human rights, though this does not extend to observance. The rights guaranteed in international law become effective when they are operationalized by legal and policy instruments at the level of the nation-state.

The most developed international system of legal human rights protection is the European Convention for the Protection of Human Rights and Fundamental Freedoms (ECHR; Council of Europe, 1950). The ECHR provides legal protection for most of the civil and political rights within the UDHR. It covers all residents in the jurisdiction of the 47 member-states of the Council of Europe. States accept that they will not resort to torture or the death penalty; nor interfere with matters of conscience and belief, free expression, peaceful assembly, personal property, correspondence, and choice of marriage partner; nor discriminate in guaranteeing these rights. Individuals can take their case to the European Court of Human Rights, which has powers to bring member-states to account and oblige them to change their legislation.

Human Rights and Languages

The exact status of demands for ensuring that national minorities including linguistic minorities have access to the full range of human rights is contested. While there is clear recognition that there is often discrimination against minorities, there is reluctance on the part of some governments to accept the need for special measures, let alone special rights, for minorities. Consequently, the Declaration on the Rights of Persons Belonging to National or Ethnic, Religious and Linguistic Minorities (United Nations General Assembly, 1992) has not developed to the status of a convention. However, in Europe the UN declaration inspired two treaties that have particular relevance in the context of languages. The first is the European Charter for Regional or Minority Languages (ECRML; Council of Europe, 1992) and the second the Framework Convention for the Protection of National Minorities (Council of Europe, 1995). These came into force in 1998, having been ratified by about half of the member-states of the Council of Europe. Certain states, notably France and Turkey, have been reluctant to sign because they do not recognize any official classification of their citizens by ethnicity, religion, or language.

The UDHR provides a language and a discourse for naming manifestations of discrimination and denial of rights. Article 2 affirms equal entitlement to all the rights in the Declaration and specifically includes language as one of several grounds that must not be used to justify denial of equal rights. It was considered necessary to state this because language may be a factor in ensuring, for example, equality before the law (Article 7) and a fair hearing (Article 10). Consequently, Article 14 of the ICCPR and Article 6 of the ECHR insist on prompt and detailed information to be provided to any accused in a language they understand and on the free assistance of an interpreter. The principle here is equality in the right to justice rather than the right to use any given preferred language. Indeed, the right does not extend to the use of the mother tongue in court proceedings and is considered to be satisfied if the accused has access to a bilingual lawyer (Henrard, 2001).

Other rights of particular concern to linguistic minorities are the right of freedom of expression and the right to receive and impart information (UDHR, Article 19), the right of freedom of peaceful assembly (UDHR, Article 20), and the right to participation in government and public service (UDHR, Article 21). The human rights of children include the right to a name (CRC, Article 7), the right to education, and the right to receive an education that respects the child's "own cultural identity" (CRC, Article 29). Children from

minority groups have “the right, in community with other members of his or her group, to enjoy his or her own culture, to profess and practise his or her own religion, or to use his or her own language.” This echoes the same commitment, extending to all persons belonging to minorities, already part of the International Bill of Rights (ICCPR, Article 27).

Linguistic Human Rights

The concept of linguistic human rights is a shorthand expression not recognized specifically in international human rights instruments. It is associated particularly with the pioneering work of Skutnabb-Kangas and Phillipson (1995). It brings together lawyers and applied linguists to provide the conceptual underpinning to a political and militant project to combat injustices to members of linguistic minorities and to curb the assimilationist trends that threaten the existence of numerous languages in the world (Skutnabb-Kangas, 2000).

It is closely associated with a number of recognized approaches, such as the rights of persons belonging to linguistic minorities (United Nations General Assembly, 1992) and the concept of minority languages (Council of Europe, 1992). The principle of protection for minorities predates human rights instruments, having been elaborated under the League of Nations in the 1930s. Claims to linguistic human rights are based on rights to freedom from forced assimilation to a majority culture.

Following a close reading of relevant instruments of international law, Henrard defines a minority as “a population group with ethnic, religious and linguistic characteristics differing from the rest of the population, which is non-dominant, numerically smaller than the rest of the population and has the wish to hold on to its separate identity” (2001, p. 43). Minority rights may be conceptualized as ensuring equal human rights to persons belonging to minorities. Just as women and children have specific human rights conventions, so it is recognized that minorities may face discrimination even when granted formal equality if this is at the expense of forced assimilation. Minorities may require measures that promote substantive as well as formal equality in access to rights. The principle of equal access to rights is also a limiting one and does not imply privileges or rights additional to those that may be claimed by all human beings.

Although the concept of minority rights and of cultural rights, which includes language rights, is well established in international law, there is not universal recognition that such group rights are in fact human rights. By definition human rights apply to individual human beings and not to collectivities (Donnelly, 2003). In fact, as secular states such as France and Turkey conceive of human rights, the concept of rights for groups or communities is problematic since it is also a fundamental human right to be able to leave or disassociate oneself from a group, including religious, ethnic, and language groups, which may be oppressive. Since human rights apply equally to all human beings they are exercised in a social context of awareness of the rights of others. Although freedom of expression in a language is also archetypically a collective cultural activity, the right may be claimed by individuals as part of a group rather than by a group to protect itself (Reidel, 2010). This conception of language rights allows for multiple identities and avoids essentializing (Sen, 2006).

Examples of situations that concern the use of language and have been proposed as denials of linguistic human rights include: refusal of official recognition to a name because it is associated with a minority (e.g., Kurdish names in Turkey); failure to provide support within the education system for speakers of foreign or minority languages; banning communication in certain languages in school classrooms and playgrounds and for prison visitors (Skutnabb-Kangas & Phillipson, 1995).

The first of these issues, regarding naming, may be presented as a human rights issue insofar as the state’s regulations on naming discriminate against names associated with

a minority. The use of a personal name is closely associated with identity and sense of personal dignity. The Convention on the Rights of the Child guarantees the right to a name, but it does not specify the right of parents to unrestricted choice of name. Opposing such linguistic discrimination is part of a wider struggle for justice and human rights.

The second issue can be framed in terms of the right to education. Children whose mother tongue is not the language of the education system may well require support in order fully to benefit from the educational opportunities offered. This applies both to migrants and to minorities. However, there are many ways in which language support may be provided and, although education in the medium of the mother tongue is in the best interests of the child (a principle of children's rights), there may also be circumstances when the disproportionate cost of providing it might draw resources away from other equally deserving children. This is a political issue that may gain purchase from using a human rights claim in circumstances when it is one of a number of discriminations. It is noticeable, however, that there is no attention to the languages of migrants in the European Charter for Regional or Minority Languages. Migrant language communities have to rely on general human rights instruments to support their struggles.

The third issue of banning the use of certain languages in schools and prisons is certainly a curtailment of freedom of expression that is hard for a liberal state to justify. Whether these examples can helpfully be bundled together within a concept of linguistic human rights, rather than just linguistic rights, is contestable. One key issue is the status claimed for languages associated with ethnic minorities and the prioritization of these over other language struggles including access within a given language community to powerful varieties of language. Blommaert observes that claims for linguistic human rights may originate in or be allied to "politicized narratives produced by politically mobilized ethnolinguistic groups with a developed political ideology that celebrates language as the distinctive feature of nationhood" (2001, p. 136).

Conclusion

It is undoubtedly the case that, where nation-states have been constituted around a dominant national language, freedom of expression and freedom of information in minority languages including migrant languages has been a site of struggle. In many cases this has been linked to campaigns for autonomy or independence. Identification with separatist movements renders the concept of linguistic human rights politically controversial. What a focus on minority languages within a human rights regime may facilitate is an awareness of the kinds of discrimination that may occur and those areas of public life including education, the judiciary, administrations, media, cultural activities, and economic and social life where dominant monolingualism may be discriminatory (Council of Europe, 1992).

Hyland, Ken

PILAR MUR DUEÑAS

Ken Hyland (b. 1951), a well-known and frequently cited scholar in English for academic purposes (EAP) research, has contributed significantly to his field by putting forward comprehensive and well-structured analytical frameworks. His research has aimed at discerning the discursual encoding of the writer–reader relationship, which, in the academic sphere, influences and is influenced by disciplinary membership and the intended audience. Hyland’s research has continuously underlined the interpersonal component of academic written exchanges. For a long time it was believed that scientific and academic knowledge was objectively and impersonally presented as a mere reflection of an external reality. However, due to a large extent to Hyland’s groundbreaking research, it is now well attested that knowledge is socially constructed and that certain discursual conventions and expectations need to be met for a text to be judged as credible and persuasive by the writer’s peers. In this context, Hyland has had a large role in unveiling the interpersonal forces driving academic communication.

One area of inquiry to which Ken Hyland has made significant contributions is in the study of what is called *metadiscourse*. Metadiscourse refers to “those aspects of the text which explicitly refer to the organisation of the discourse or the writer’s stance towards either its content or the reader” (Hyland, 2000, p. 109). Drawing on previous accounts of metadiscourse (Vande Kopple, 1985; Crismore & Farnsworth, 1990; Crismore, Markkanen, & Steffenson, 1993; Mauranen, 1993), Hyland refined its categories and established a framework which has proved remarkably fruitful and has inspired a great deal of academic discourse research. Hyland (1998, 2000) organized metadiscourse into textual and interpersonal categories. Within textual metadiscourse he included the analysis of logical connectives (which express a connection between ideas), frame markers (aimed at structuring the discourse into discourse acts or text stages and which include sequencing markers, label stages, announcements of goals, and topic shifts), endophoric markers (which refer to other parts of the discourse), evidentials (indications of source materials), and code glosses (which introduce further information for the reader to grasp the writer’s intended meaning). Under interpersonal markers he grouped hedges (terms expressing the writer’s lack of full commitment to the accompanying proposition), boosters (elements marking certainty and conviction), attitude markers (indications of affective evaluation, including attitude verbs, necessity modals, and adjectives), relational markers (devices intended to bring readers into the text and which comprise second person pronouns, question forms, imperatives, and digressions), and person markers (references to the author(s) through first person pronouns and possessive adjectives).

Hyland then argued for a stronger interpersonal view on metadiscourse, where metadiscourse is understood as the cover term for discourse devices which embody the writer–reader interaction (Hyland, 2005a). Hyland and Tse (2004) presented a revised interpersonal model of metadiscourse, in which they articulated a distinction between external and internal text features, metadiscourse being restricted to those features which make an internal (in-text) reference.

Much of Hyland’s work has been devoted to exploring these metadiscourse categories as deployed in a wide array of academic genres, mostly in research articles, but also in

abstracts, textbooks, master and PhD dissertations, acknowledgments, final-year student reports, textbooks, and book reviews. His analyses look into the ways in which writers build convincing arguments and how metadiscourse contributes to positioning the author in relation to the text and in relation to readers in ways that are conventional and expected in particular disciplinary communities. Hyland's research findings have had important influences on academic language teaching.

Hyland's (2005b) model of writer–reader interaction based on the concepts of stance and engagement also provides a key framework for the analysis of academic communication. Stance is the expression “of a textual ‘voice’ or community recognized personality” (Hyland, 2005b, p. 176) and encompasses the use of hedges, boosters, attitude markers, and self-mentions. Engagement, on the other hand, is the way through which “writers relate to their readers with respect to the positions advanced in the text” (Hyland, 2005b, p. 176). It encompasses the use of reader pronouns, directives, questions, and personal asides. With this model Hyland stresses how scholars need to offer a novel and valuable contribution to the body of disciplinary knowledge in rhetorically appropriate terms. This entails projecting a credible authorial voice, making appropriate judgments, establishing their credentials, and opening space for alternative views and evaluations, while claiming solidarity with, responding to, and bringing in their potential readers.

Hyland has applied the models outlined above in numerous corpus-based studies. His cross-disciplinary analyses have mostly, but not solely, focused on the analysis of a corpus of 240 research articles from 8 disciplines (mechanical engineering, electrical engineering, physics, biology, marketing, philosophy, sociology, and applied linguistics), totalling 1.4 million words. He has frequently complemented the quantitative data analyses with valuable ethnographic data taken from interviews with informants in the above disciplines following a semi-structured format. This process has enabled him to dig deeply into the discursive practices of the members of these communities and discover the rhetorical preferences of academic discourse communities. Hyland (2005) has reported a higher inclusion of interactive and interactional features in the soft-discipline (e.g., philosophy or sociology) texts than in the hard-discipline (e.g., physics or engineering) texts. The higher degree of interactional features, especially hedges and engagement markers, in the soft sciences is interpreted by Hyland to result from the more interpretive, less abstract nature of knowledge in the social sciences and humanities. Alternative voices and appeal to solidarity with readers are claimed to be strong in the social sciences and humanities. On the other hand, writers in the hard disciplines tend to downplay interactional positions, which results in a less reader-inclusive rhetoric stressing the impartiality and linearity of science production. His results also suggest differences in the use of interactive features in research articles across different disciplines, mainly regarding endophorics (i.e., markers that refer to information on other parts of the text), and especially, evidentials (i.e., markers which indicate the source of information from other texts). Academics in the more discursive, soft disciplines need to more clearly establish the contextual link between their research and previous work, as knowledge tends to be recursive, rather than cumulative. Overall, this comparison of discourse choices in research article writing across several fields has enabled Hyland to identify relationships between the ways in which disciplines see the world and conduct research, and the ways they socially turn this research into publishable articles.

Hyland has extended a cross-disciplinary approach to the study of other academic genres in addition to the research article, namely textbooks (Hyland, 2005), second language (L2) postgraduate writing (Hyland, 2004; Hyland & Tse, 2004), and book reviews (Tse & Hyland, 2006, 2008, 2009). He explains differences in the use of metadiscourse markers in textbooks and in L2 master and doctoral dissertations in soft versus hard disciplines as a direct consequence of the importance that personal interpretation plays in the former, more discursive disciplines. Hyland stresses how these genres are rhetorically constructed in

ways that mirror the building of knowledge in professional academic genres in a particular disciplinary community. Interestingly, book reviews have been approached from a double analytical perspective, taking both discipline and gender as variables (Tse & Hyland, 2006, 2009). In general, Hyland and his coresearcher do not find relevant gender differences in the use of metadiscourse features in philosophy, sociology, and biology book reviews. Male and female reviewers seem overall to portray themselves and their readers and express their views in rather similar ways, although to different extents in each of these three disciplines. Disciplinary affiliation, rather than gender, impinges on the reviewers' discursive choices.

Besides cross-disciplinary and gender-based analyses of academic writing, Hyland has compared student writing with professional writing (Hyland, 2009) and has explored differences between research article writing and popular writing (Hyland, 2009, 2010). According to Hyland (2009), popularizations, or science journalism, present distinctive rhetorical and discursive features from scholarly writing. Contrary to what tends to be the case in research articles, popularizations follow a deductive rhetorical pattern and present the main finding at the beginning of the text to foreground novelty. Information in these popular texts is framed so that it is likely understood by the nonexpert audience; thus, definitions and explicit indications of links between ideas become key rhetorical strategies. Also, the source of the information is commonly stressed in popularizations as a way of achieving reliability. Finally, the different communicative purpose of popularizations leads to "glamorizing material for a wider audience" (Hyland, 2009, p. 170). This includes an array of attitude markers expressing the writer's affection as well as a low number of uncertainty features. The different communicative purpose of popular science inevitably calls for different discursive and rhetorical features from scientific research reporting.

This cross-generic approach to the analysis of academic discourse has led Hyland (2010) to propose the term *proximity* to subsume both the way writers show authority by displaying an array of disciplinary conventions (proximity of membership) and the way writers show the material in such a way that it meets readers' expectations (proximity of commitment). Proximity is achieved differently in popular science and in research articles. Hyland finds that in popular science articles proximity entails the presentation of research so that it is easily processed by nonspecialists, whereas in research articles proximity entails the presentation of research following the conventions of the academic disciplinary community (i.e., displaying familiarity with the position of one's research in relation to previous literature, describing methods accurately, presenting results in a cautious way, and making claims which are supported on the basis of these). Proximity, explored through the analysis of organization, argument, credibility, stance, and engagement, helps unveil the different ways in which writers negotiate meaning with different audiences and for different purposes.

Through his overall analysis of academic discourse in general and through his detailed cross-disciplinary, cross-gender, and cross-generic studies of academic interaction in particular, Hyland has shown how language plays a crucial role in the social practices of the academia. It is through discourse that academics respond to the expectations, beliefs, and conventions of a given discipline, create their own identities and engage with their readers, constructing an effective argument. Thus only by appropriately managing discourse can academics significantly contribute to the process of knowledge creation in their communities.

Ken Hyland has shaped the recent directions of research on and teaching of written academic English. Besides his contributions to the field of EAP through published articles, chapters, books, and edited volumes, he was also the founding coeditor of the *Journal of English for Academic Purposes* for seven years and he is now coeditor of *Applied Linguistics*. All in all, his more than 15 books and over 140 articles and chapters have established him as a leading scholar in academic discourse studies.

Hymes, Dell

SUZIE WONG SCOLLON

Geosemiotics

Dell Hathaway Hymes (1927–2009) was a linguistic anthropologist most widely known for developing, with John Gumperz, the study of the ethnography of communication with the mnemonic S-P-E-A-K-I-N-G (Gumperz & Hymes, 1972), discussed below. To educators he is best known for the concept “communicative competence.” He was one of very few to serve as president of the American Anthropological Association, the American Sociological Association, the Linguistic Society of America, and the American Folklore Society. He founded the journal *Language in Society* in 1972 and edited it for two decades. Hymes is known primarily for advocating the study of language as a social phenomenon, the study of linguistic relativity or relations between language and culture, and the problem of equality of linguistic resources.

Background

Growing up in Portland, Hymes attended Reed College for a year before being drafted into the Army for two years of service in South Korea. Returning to Reed, he completed his BA in 1950, with a critique of Christopher Caudwell as an undergraduate honors thesis in literature and anthropology. He learned from Professor Lloyd Reynolds the value of looking for antecedents of social phenomena in historical formations. Grounded in Marxist theory and informed by his experience in the US Army, Hymes sought to use anthropological knowledge to improve society and bring about equality. As a student he urged activism, a stance that brought trouble for him during the McCarthy era (Scollon, 2004). After introductions to Warm Springs Indians by Professor David French, he spent four decades working with recorded texts of indigenous languages of the Pacific Northwest.

From Reed Hymes went to Indiana University to study linguistics and folklore with Karl Voegelin, a student of Edward Sapir. His doctoral dissertation, completed in 1955, analyzed Kathlamet locative postpositions. A course with Harry Hoijer in Athabaskan at UCLA led to Hoijer recommending Hymes when Harvard was looking for a social scientist; he taught at Harvard from 1955 to 1960, then at University of California, Berkeley from 1960 to 1965. He then taught in the anthropology department at University of Pennsylvania, moving to folklore and folklife in 1972, and becoming dean of the school of education in 1975. He moved to the University of Virginia in 1987, retiring in 1998 as Commonwealth professor of anthropology emeritus.

Contribution

Perhaps his most widely recognized contribution is the notion of “communicative competence,” put forth to challenge Chomsky’s dichotomy of competence versus performance. He underlines child socialization as the heart of descriptive sociolinguistics:

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

© 2013 Blackwell Publishing Ltd. Published 2013 by Blackwell Publishing Ltd.

DOI: 10.1002/9781405198431.wbeal0519

Within the social matrix in which it acquires a system of grammar a child acquires also a system of its use . . . In such acquisition resides the child's sociolinguistic competence (or, more broadly, communicative competence), its ability to participate in its society as not only a speaking, but also a communicating member. (1974, p. 75)

He cited Malinowski, calling language a "mode of action" (1974, p. 75).

Hymes advocated an ethnographic approach to "investigate directly the use of language in contexts of situation, so as to discern patterns proper to speech activity" (1974, p. 3). Such functional and structural analysis was advocated by the Prague Circle and by Sapir (1974, pp. 5–6). An ethnography of speaking "would be a linguistics that had discovered ethnographic foundations, and an ethnography that had discovered linguistic content, in relation to the knowledge and abilities for use of knowledge (competence) of the persons whose communities were studied" (1974, p. 116).

The interaction of language and social life is thus at the heart of the ethnography of speaking or, more broadly, the ethnography of communication. Gumperz and Hymes saw the ethnography of communication in part as a restoration of attention to situated speaking in the wake of Chomsky's isolation of language and its study as an autonomous discipline. They were interested in the ecology of language, its relation to both natural and social environments. A concern with participants and the functions communicative events serve for them was fed by Kenneth Burke's focus on language as action arising from motives rather than simple physical motion (Hymes, 1974, p. 21).

Hymes used ethnography of communication to make a significant contribution to the theory of linguistic relativity, arguing that the effect of a language in shaping one's worldview and behavior would depend on the age and other circumstances under which one learned the language, whether it was a first or second or "nth" language, which generations spoke it and how fluently and how effectively, and so forth. A speaker's ability with a language would influence its effect on his or her thought or reality.

Though Hymes did not believe in the strong version of the Sapir-Whorf hypothesis, that the language one speaks determines one's thought and reality, he did have to reorient his thinking in order to understand the way speakers of Kathlamet Chinook talk about going from here to there or from there to here. Because, as he pointed out, there are no grammars written by native speakers, linguistic anthropologists had to figure out how aboriginal languages work by studying texts transcribed from oral performance.

With Dennis Tedlock and others, Hymes pioneered ethnopoetics, the treatment of oral narrative as lyric drama rather than prose (Hymes, 1981). Utterance-initial particles in Native American oral narrative performance mark change of scene or action, with structural units of two and four or three and five parts. "Narrative segments are marked at the beginning by a standard particle sequence" (Hymes, 1981, p. 103). Patterns emerge among lines rather than within lines as in metered verse, and he called these "measured verse" (Bringinghurst, 2008, p. 221). The material came largely from Kathlamet texts dictated to Boas by Q'elti, a master storyteller, over a hundred years ago.

Hymes encouraged anthropologists to study not only primitive peoples but contemporary government and other institutions, and was particularly concerned that linguistic anthropologists work to prevent further destruction using nuclear weapons. As dean of education at the University of Pennsylvania, he and his students sought to apply the ethnography of communication to education in and out of the classroom. Susan Philips (1972, 1983) showed that communicative patterns learned by Warm Springs Indians at home carried over into the classroom, where they interfered with learning behavior expected by non-aboriginal teachers. Hymes introduced this work, saying, "an understanding of rules of speaking is indispensable to understanding failures and to increasing success in bicultural education" (1974, p. 124).

Components of Speaking

As a mnemonic to conveniently classify the components of situated communication, Hymes devised a SPEAKING grid on which to plot relationships among components:

- S Setting
- P Participants
- E Ends
- A Act sequence
- K Key
- I Instrumentalities
- N Norms
- G Genres

Setting, for example, can be related to participants, genres, or any of the other components. For instance, in central Oregon signs are placed more plentifully in the town of Madras than on the Warm Springs Indian reservation, where they occur only at sites frequented by strangers (Hymes, 1996, pp. 39–40). Signs can be considered a *genre*, defined by combinations of ends, placement, and means (writing and graphics).

Participants relates to setting when children in school speak Standard English in the classroom and other languages and codes on the playground. The same participants communicate differently in distinct settings, with different instrumentalities.

Ends and *key* relate when children attempt to humor their elders by coaxing cookies out of them, say.

Norms for speaking may differ with male relations present or absent, with women from some societies more willing to speak as authorities when no men are present.

Conclusion

Hymes's contribution to sociolinguistics centers on the notion of communicative competence, with which he called into question Chomsky's distinction between competence and performance. Appropriate performance, he argued, is part of communicative competence. Knowing how and when to tell a story is more important than being able to generate innumerable sentences that make no sense except as examples of aberrant usage.

Communicative competence entails a kind of grammatical knowledge of the components of speaking, laid out in a grid of setting, participants, goals, and the rest. It is an internalization of community norms for ways of speaking, gesturing, signaling, and other modalities of communication—a grasp of the place of language in the community, its varieties, styles, genres.

An ethnography of communication which specifies the linguistic resources available to learners can help reduce linguistic inequality. This and prevention of nuclear conflict were among Hymes's principal concerns. These were interwoven with the theory of linguistic relativity, which he broadened to include the ways of speaking of an individual: in which communities at which stages of life she learned particular linguistic varieties.

Hymes was profoundly influenced by his study of Native American folklore as well as grammatical categories. In particular, the Sun's myth was indelibly entwined with the bombing of Hiroshima. In one of his last public presentations to linguists, he read part of his translation of the myth. The destruction of a whole people that it conveyed brought to his mind not only Hiroshima but the war in Iraq. His relating of morphology to global affairs was an inspiration to many linguistic anthropologists.

Identities and Language Teaching in Classrooms

DIANE DAGENAIS

What is the relationship between learners' identities and their language-learning experiences? How are identities constructed in language classrooms and what does this imply for students and teachers? Over the last decade, applied linguists have paid increasing attention to questions such as these, as have scholars in such related fields as second language acquisition (SLA), language education, and sociolinguistics. Studies examining the links between learner identities and language-learning contexts have revealed that the ways learners define themselves, are defined by others, and are positioned in social interaction have an observable impact on their learning experiences. This body of scholarship has contributed to advancing new theoretical insights on identity construction in language-learning situations.

Identity and Language Learning: Theoretical Developments

Recent interest in social theories of identity and language learning marks a departure from earlier discussions of identity in research that attended primarily to individual learners' personality traits, motivations, and learning styles. As Block (2007) signaled, identity issues were raised more or less directly over 30 years ago in a series of psycholinguistic studies of second-language learning, but were never fully taken up at the time. He noted, for example, that Lambert (1972) wrote about the development of a bicultural identity among French/English bilinguals; Schumann (1978) proposed that second language learning was related to a sense of self and a process of acculturation; and several others examined how affective factors impact on language learning. In this research, identity was considered as a variable associated with an individual's language-learning strategies, language and ethnic identity were correlated, and ethnolinguistic groups were seen as cohesive entities.

These perspectives were first challenged by Norton Peirce (1995), who called for the development of a more nuanced theory of identity that could better account for the relationship between language learners and their learning contexts. To articulate how larger social forces shape local learning situations, she drew on poststructuralist theories of language as embedded in relations of power and proposed investment as a sociological construct to complement the notion of individual motivation advanced in social psychology. She argued that learners who are highly motivated might not invest in learning language in environments that are problematic for them and do not allow them to see possibilities for a return on their investment.

Since then, several researchers (e.g., Norton, 2000; Toohey, 2000; Pavlenko & Blackledge, 2004; Block, 2007) have helped advance social theories of identity that view language as a discursive practice of negotiating meanings and social positioning and consider linguistic groups to be heterogeneous. Identity construction is described as a process of imagination whereby learners define themselves in relation to others with reference to past, present, and future imagined communities (Kanno & Norton, 2003). In other words, as people learn a language, they refer to their past language-learning experiences and imagine how the target language might allow them to affiliate with new social networks.

The Construction of Learner Identities

Observational and interview data from qualitative studies of language learning conducted in multilingual contexts have shown how people respond to the identities attributed to them. Adult immigrant English-language learners who participated in Norton's (2000) study were seen to adopt a number of strategies to resist stigmatizing identities that positioned them in a negative light in social interactions with employers, instructors, and other language learners. Multilingual adolescents in Lamarre and Dagenais's (2003) study rejected attempts to associate them with one linguistic or cultural group, preferring instead to define themselves in relation to multiple groups and within a transnational frame of reference that crossed boundaries of nationality, ethnicity, and language. Similarly, contributors to Pavlenko and Blackledge's (2004) edited volume examined how identities are negotiated in varying ways in relation to discourses of discrimination and empowerment in a wide range of learning situations internationally.

Longitudinal studies conducted in schools have documented how students are assigned fixed identities that serve to rank them according to academic competencies and language proficiencies. Based on ethnographic methodologies, this research reveals how bilingual and multilingual youth are afforded limited opportunities at school to display linguistic and cultural knowledge acquired in family and community settings. Toohey's (2000) study with English-language learners in kindergarten demonstrated how those who were identified as less skilled were marginalized and had fewer opportunities to engage in language interactions in the classroom. Likewise, analyzing data from a study of the language practices of French immersion students from immigrant families, Dagenais, Day, and Toohey (2006) found that, while these children might identify themselves in small-group interactions as multilinguals who were literate in multiple languages, teachers who focused only on the language of instruction and participation in large-group activities overlooked these expressions of identity and in some cases even defined these youngsters as at risk academically. In her analysis of social-studies lessons in an urban high school, Duff (2002) examined how one teacher and second language learners in her class positioned themselves discursively in teacher-led discussions. This study revealed that, when the teacher tried to draw on students' background knowledge and experiences, some learners resisted this and chose to not reveal aspects of themselves in class. Duff's research underlined the importance of understanding why students may do this and considering what identities they may or may not want to adopt in classroom interactions.

Supporting Student and Teacher Identities in Inclusive Classrooms

In light of such research results, some teacher-researcher groups have been established in Canada recently with the objective of creating classrooms that are more inclusive of diverse identities and language practices. Partners in these projects have documented home- and community-language practices to engage children in multilingual and multimodal literacy activities at school.

For example, in the Multiliteracies Project, a multisite collaboration between groups of students, educators, and parents in Toronto and Vancouver, children produced "identity texts" (Cummins, 2006) at school in which they expressed aspects of their experiences using a range of modalities. To create these texts, the children included various media such as oral and written language, sound, visual images, and digital technologies and they were encouraged to draw on whatever linguistic and cultural resources were available to them.

Similarly, in a Toronto primary school that serves as the site for a project entitled “Emergent Multiliteracies in Theory and Practice: Multicultural Literacy Development at Elementary School,” students, educators, and researchers have collaborated over a number of years to explore how diverse identities might be recognized at school through multi-modal literacy activities (Lotherington, Holland, Sotoudeh, & Zentena, 2008). Partners in the project have worked on rewriting traditional children’s stories to include varied cultural reinterpretations, multilingual versions, and a broad array of visual media and digital technologies.

In an action-research project entitled “Éveil aux langues et à la diversité linguistique chez des élèves du primaire dans deux métropoles canadiennes,” students enrolled in French-language primary programs in Montreal and Vancouver worked with their teachers and researchers to photograph the multilingual landscape of their communities (Dagenais, Moore, Sabatier, Lamarre, & Armand, 2008). They also examined a variety of written, audio, and visual materials in several languages in the context of language-awareness activities aimed at including multiple languages in the curriculum; developing an understanding of the different groups with which children and teachers identify and affiliate; and stimulating a broader interest in local, national, and international linguistic and cultural diversity.

Researchers working on a project situated in Vancouver entitled “A Sociocultural Investigation of Literacy Instruction for Children Learning English as a Second Language” collaborated with teachers, children, and parents to produce inventories of outside-school multilingual literacy practices in the community (Smythe & Toohey, 2009). They found that documenting these practices provided students with powerful opportunities to enhance their spoken and written competencies as they photographed their communities and created other visual representations of their lives and, to do so, relied on linguistic and cultural resources rarely visible in school.

Innovative projects such as these are promising because they examine critically whether activities in which students and teachers share aspects of their identities and cultural knowledge enable learners to engage more actively in classroom interactions.

Conclusion

In sum, in contrast to earlier sociopsychological theories of identity as individual attribute, contemporary theories of identity are based on poststructuralist perspectives that consider the relationships between identity construction and issues of power in social contexts, including educational and classroom situations. Identities are seen as dynamic, multiple, and sometimes conflicting social constructions, and in classrooms the identities attributed to learners and those they take up themselves have been shown to affect their investment and participation in language interactions. Learners are considered to have agency and to be capable of resisting problematic identities to negotiate more powerful social positions, as the situation allows. In keeping with this perspective, teams of teachers and researchers have begun exploring possibilities for recognizing how diverse identities as well as linguistic and cultural practices and affiliations developed out of school might serve as pedagogical resources and facilitate learning in language classrooms.

Identity and Second Language Acquisition

BONNY NORTON

To understand the vibrant and increasing interest in identity and second language acquisition (SLA), it is important to understand changing conceptions of the individual, language, and learning in the field. Each of these areas is associated with broader trends in the social sciences, which represent a shift in the field from a predominantly psycholinguistic approach to SLA to include a greater focus on sociological and anthropological dimensions of language learning, particularly with reference to sociocultural, poststructural, and critical theory (Norton & Toohey, 2001; Block, 2007b; Morgan, 2007). SLA researchers who are interested in identity are interested not only in linguistic input and output in SLA, but in the relationship between the language learner and the larger social world. They question the view that learners can be defined in binary terms as motivated or unmotivated, introverted or extroverted, without considering that such affective factors are frequently socially constructed, changing across time and space, and possibly coexisting in contradictory ways within a single individual. These researchers have examined the diverse social, historical, and cultural contexts in which language learning takes place, and how learners negotiate and sometimes resist the diverse positions those contexts offer them.

Many researchers interested in identity and SLA are also interested in the extent to which relations of power within classrooms and communities promote or constrain the process of language learning. It is argued that the extent to which a learner speaks or is silent, or writes, reads, or resists, has much to do with the extent to which the learner is valued in any given institution or community. In this regard, social processes marked by inequities of gender, race, class, ethnicity, and sexual orientation may serve to position learners in ways that silence and exclude. At the same time, however, learners may resist marginalization through both covert and overt acts of resistance. What is of central interest to researchers of second language identity is that the very articulation of power, identity, and resistance is expressed in and through language. Language is thus more than a system of signs; it is a social practice in which experiences are organized and identities negotiated.

Theoretical Framework

Changing conceptions of the individual, language, and learning in the social sciences have had a significant impact on theories of identity in the field of SLA.

Changing Conceptions of the Individual

In the 1970s and 1980s, much research on language learning investigated the personalities, learning styles, motivations, and other unique characteristics of individual learners, and conceived of language learners with reference to relatively fixed and long-term traits. Such research was consistent with humanist conceptions of the individual dominant in Western philosophy, which presupposed that every person—the “real me”—had an essential,

2 IDENTITY AND SECOND LANGUAGE ACQUISITION

unique, fixed, and coherent core. In more recent theory, as Weedon (1997) notes, poststructuralism depicts the individual as diverse, contradictory, dynamic, and changing over historical time and social space. The individual is conceived of as a "subject," in that the individual can be subject *to* a set of relationships in one social site, or subject *of* a set of relationships in another social site. In the former, the individual would be in a relatively powerless subject position; in the latter, the individual would have greater power relative to other individuals. The central point is that the individual's "subjectivity," or what could be considered their "identity," is always constituted in relational terms; the individual never stands apart from the social world, but is always an integral and constitutive part of it.

Such theory has great relevance for SLA theory in that it provides insight into the conditions under which language learners can speak, read, or write. In those contexts in which a language learner is valued, and is in a subject position of relative power, the learner will be encouraged to engage in social interaction; in those contexts in which a learner is marginalized and powerless, opportunities for social interaction will be more limited. However, in poststructuralist theory, structural constraints and social conditions are never entirely determined. Through human agency, language learners who struggle to speak from an identity position of relative powerlessness may be able to reframe their relationship with their interlocutors and claim alternative, more powerful identities from which to speak, thereby enhancing language learning.

Changing Conceptions of Language

Of particular interest to identity theorists is that poststructuralism foregrounds the central role of language in theorizing the relationship between the individual and the social world: "Language is the place where actual and possible forms of social organization and their likely social and political consequences are defined and contested. Yet it is also the place where our sense of ourselves, our subjectivity, is constructed" (Weedon, 1997, p. 21). Poststructuralist theories of language build on, but are distinct from, structuralist theories of language, associated predominantly with the work of Saussure (1966). For structuralists, the building blocks of language structure are signs that comprise the signifier (or sound-image) and the signified (the concept or meaning). Saussure asserted that neither the signifier nor the signified preexists the other and that the link between them is arbitrary. He saw the linguistic system itself as guaranteeing the meaning of signs, and each linguistic community as having its own set of signifying practices that give value to the signs in a language. Poststructuralists, in contrast, take the position that structuralism cannot account for struggles over the meanings that can be attributed to signs in a given language. The signs /feminist/, /research/, /SLA/, for example, can have different meanings for different scholars within the same linguistic community. Thus, while structuralists conceive of signs as having idealized meanings and of linguistic communities as being relatively homogeneous and consensual, poststructuralists argue that the signifying practices of societies are sites of struggle, and that linguistic communities are heterogeneous arenas characterized by conflicting claims to truth and power.

Changing Conceptions of Learning

With reference to theories of learning, many traditional paradigms in psychological research conceive of SLA as a primarily cognitive process. More recent work has attempted to investigate language learning as a socioculturally situated social practice (see Lantolf, 2000; van Lier, 2004; Zuengler & Miller, 2006). This research conceptualizes second language learning as relational activity that occurs between specific speakers situated in particular sociocultural contexts. Notions of the sociality of learning (Vygotsky, 1978) are particularly

important in this regard, in that they contest views of language learning as individual minds acquiring linguistic, or even sociolinguistic, competence. Learners are seen as members of social and historical collectivities, who appropriate the practices of a given community, rather than as individual language producers. Anthropologists Lave and Wenger (1991) argue that learning is an integral and inseparable part of social practice, as newcomers learn from old-timers in the performance of community practices. Their notion, "legitimate peripheral participation," represents their view that communities are composed of participants who differentially engage with the practices of their communities, and that this engagement or participation in practice constitutes "learning." They stress the importance of local analysis of communities, and point out that conditions vary with regard to ease of access to expertise, opportunities for practice, consequences for error in practice, and so on.

Identity on the SLA Agenda

Changing conceptions of the individual, language, and learning have helped to place identity on the SLA agenda. Many scholars (Ricento, 2005; Zuengler & Miller, 2006; Block, 2007a; Swain & Deters, 2007; Menard-Warwick, 2009) cite Norton's theorizing of identity (Norton Peirce, 1995; Norton, 2000) as central in framing contemporary understanding of identity and language learning. Poststructuralist theory, particularly that associated with Weedon (1997) and Bourdieu (1991), is central to Norton's theories of identity, which she presents as multiple, a site of struggle, and subject to change. Of central interest are the ways in which language learners understand their relationship to the social world, how that relationship is constructed across time and space, and how the learner understands possibilities for the future. Every time language learners interact in the second language, whether in the oral or written mode, they are engaged in identity construction and negotiation.

Norton's construct of "investment," which complements constructs of motivation in SLA (Dornyei, 2001), is inspired by the work of Bourdieu (1991), and signals the socially and historically constructed relationship of learners to the target language and their often ambivalent desire to learn and practice it. If learners "invest" in the target language, they do so with the understanding that they will acquire a wider range of symbolic and material resources, which will in turn increase the value of their cultural capital. While psychologists might ask, "To what extent is the learner motivated to learn the target language?" the identity theorist asks, "What is the learner's investment in the target language practices of this classroom?" A learner may be a highly motivated language learner, but may nevertheless have little investment in the language practices of a given classroom or community, which may, for example, be racist, sexist, elitist, or homophobic. There may also be important discrepancies between a language learner's conception of good teaching, and the practices of a given classroom. Thus, despite being highly motivated, a learner could be excluded from the language practices of a classroom, or perhaps resist certain classroom practices, and in time be positioned as a "poor" or unmotivated language learner. The construct of investment has sparked considerable interest and research in the field (McKay & Wong, 1996; Skilton-Sylvester, 2002; Pittaway, 2004; Haneda, 2005; Cummins, 2006; Potowski, 2007; Arkoudis & Davison, 2008; Norton & Gao, 2008).

An extension of interest in identity and investment concerns the imagined communities that language learners may aspire to join when they learn a new language. The term "imagined community," originally coined by Anderson (1991), was introduced to the language-learning community by Norton (2001), who argued that in many language classrooms, the targeted community may be, to some extent, a reconstruction of past communities and historically constituted relationships, but also a community of the imagination, a desired

community that offers possibilities for an enhanced range of identity options in the future. These ideas, inspired also by Lave and Wenger (1991) and Wenger (1998), are more fully developed in Kanno and Norton (2003) and Pavlenko and Norton (2007), and have been productive across diverse research sites (Carroll, Motha, & Price, 2008; Dagenais, Moore, Lamarre, Sabatier, & Armand, 2008; Kendrick & Jones, 2008). An imagined community assumes an imagined identity, and a learner's investment in the second language can be understood within this context.

There is now a wealth of research that explores the relationship between identity and language learning, testament to the fact that issues of identity and power are now central to theories of language learning and teaching. Key books include Norton (2000), Toohey (2000), Pavlenko and Blackledge (2003), and Block (2007a). Further, the award-winning *Journal of Language, Identity, and Education*, launched in 2002, ensures that issues of identity and language learning will remain at the forefront of research on SLA, applied linguistics, and language education in future years. As discussed in the next section, there is an increasing interest in identity categories in language learning, identity and resistance in language learning, and identity and digital language learning.

Key Directions in Identity Research

Identity Categories

While much research on language and identity explores the multiple and intersecting dimensions of learners' identities, there is a growing body of research that seeks to investigate the ways in which particular relations of race, gender, class, and sexual orientation, among others, may impact the language-learning process. Innovative research that addresses these issues does not regard such identity categories as "independent variables," but rather as sets of relationships that are socially and historically constructed within particular relations of power. Three key books, all published in 2009, exemplify interest in race, gender, and sexual orientation, respectively (however, see Norton, 2010, for a broader overview).

In the book on *Race, Culture, and Identities in Second Language Education*, edited by Kubota and Lin (2009), authors from diverse regions of the world address the extent to which race, racialization, and racism are relevant to second language learning and teaching. Of central interest are the ways in which Whiteness influences students' and teachers' sense of self, and how discourses of racialization, including colorblindness, influence the construction of language teacher and student identities. Kubota and Lin argue persuasively that issues of race have not been adequately addressed in the field, and that the colorblind perspective has important limitations. At the same time, they argue that the field should address racialized norms not only in relation to Whiteness, but in relation to the multiple and complex ways in which racism is practiced in diverse sites and communities.

With regard to gender, Menard-Warwick (2009) examines the ways in which the complex gendered life histories of Latin American immigrant adults in the USA shape their participation in both the English-language classroom and the education of their children. Although these adult immigrants saw themselves positioned in multiple ways by their community and by the larger society, it was gender identities that emerged as a key factor in their decisions to pursue English-language competence at particular times in their lives. Menard-Warwick found that different adults understood gendered practices in different ways, which depended on their unique histories and present circumstances. She also found that gendered discourses strongly influenced classroom practice, but that students did not engage with these discourses in uniform or consistent ways.

In a similar spirit, Nelson (2009) explores the extent to which sexual orientation might be an important identity category in the language classroom. Of central interest is the way

in which a teacher can create a supportive environment for learners who might be gay, lesbian, or transgendered. Nelson contrasts a pedagogy of inquiry, which asks how linguistic and cultural practices naturalize certain sexual identities, most notably heterosexuality, with a pedagogy of inclusion, which aims to introduce images as well as experiences of gays and lesbians into curriculum materials. Nelson's approach can fruitfully be applied to other issues of marginalization, helping learners to question normative practices in the target culture into which they have entered.

Identity and Resistance

The relationship between language, identity, and resistance has become a compelling and fruitful area of research in language education. While larger structural constraints and classroom practices might position learners in undesirable ways, learners, with human agency, can resist these positions in innovative and unexpected ways, as the following two examples illustrate. In exploring what he calls the subversive identities of language learners, Canagarajah (2004) addresses the intriguing question of how language learners can maintain membership of their vernacular communities and cultures while still learning a second language or dialect. He draws on his research with two very different groups, one in the USA and the other in Sri Lanka, to argue that language learners are sometimes ambivalent about the learning of a second language or dialect, and that they may resort to clandestine literacy practices to create "pedagogical safe houses" in the language classroom. In both contexts, the clandestine literacy activities of the students are seen to be forms of resistance to unfavorable identities imposed on the learners. At the same time, however, these safe houses serve as sites of identity construction, allowing students to negotiate the often contradictory tensions they encounter as members of diverse communities.

The second example of identity and resistance is drawn from Talmy (2008), who investigated the multiple ways in which English-language learners in a Hawaiian high school resisted being positioned as "ESL students" in their dedicated ESL classes. While the school-sanctioned ESL student was expected to bring required materials to class, read assigned fiction, do bookwork, meet assigned dates, follow instructions, and work for the full class session, resistant ESL students engaged in a wide variety of oppositional activities, including leaving materials "at home," talking with friends, and playing cards. Talmy describes how ESL teachers began to change their practices in response to the resistance of their students, necessitating a shift in teacher identity. He also notes that the students' actions paradoxically turned the ESL program into a program that did little to meet the students' learning or educational needs.

Identity and Digital Language Learning

The affordances of digital technology have been investigated by a number of scholars interested in identity and language learning, and this trend will likely strengthen in future years. Lam (2000), for example, found that immigrant youth in the USA were fashioning identities for themselves in computer-mediated transnational networks as multilingual, multicompetent actors. In so doing, they were able to provide for themselves new language-learning opportunities that seemed denied to them in their school, in which they were stigmatized as immigrants and incompetent language users. In another part of the world, White (2007) examined two distance language-teaching programs in Australia, both of which were responding to the need for a wider range of foreign languages in schools. She concluded that as innovations in distance learning and teaching expand, it is imperative that the field find ways of addressing the philosophical, pedagogical, and professional issues that arise, and that issues of identity, for both teachers and learners, are significant

factors in each of these domains. The interest of many emerging scholars in what digital technologies may mean for language learning and learner identities will no doubt add to our increased understanding of this relationship in the future.

Conclusion

In 1997, Firth and Wagner argued persuasively that the field of SLA needed to expand its ontological and empirical base in order to become more theoretically robust. The vibrant research in identity and SLA demonstrates convincingly that language acquisition is not only a complex cognitive process, but also a profoundly social practice.

Ideology in Research Methodology

LUIZ PAULO MOITA-LOPES

Any consideration of research methodology necessarily involves accounting for ideological issues. This is so because research is carried out and reported through discourse, and discourse—that is, how we go about the world using language—is inseparable from ideology (Volosinov & Bakhtin, 1929/1981; Fairclough, 1989): “the word is an ideological phenomenon *par excellence*” (Volosinov & Bakhtin, 1929/1981, p. 31) in the sense that it brings about particular meaning effects. Therefore, research discourse is also ideological. Ideology, however, has been defined differently in philosophy (empiricist, idealist, Marxist, among other traditions) with a view to accounting for how we produce ideas in our minds on the basis of external objects and to explaining false consciousness, in some theoretical perspectives (Hawkes, 1996). Volosinov and Bakhtin’s (1929/1981) argument that we cannot escape ideology is, however, illuminating here, suggesting that our ideas, values, and views of the world are intrinsic to discourse, to how we interactionally position ourselves in the world vis-à-vis others, and, accordingly, to the choices we make in the world, including, consequently, the object of our research choices, to how we design ways of producing new knowledge.

Or, as Volosinov and Bakhtin (1929/1981, p. 95) point out: “in fact, we do not pronounce or hear words, but truth or lies, good or bad, important or trivial, pleasant or unpleasant things etc. The word is always impregnated with content or with ideological or experiential meaning.” Consequently, when we utter words in the world, we speak from a particular position, which places us ideologically in social life, bringing about particular semantic effects: “it may help to see ideology . . . as a particular set of effects within discourses” (Eagleton, 1991, p. 194). If knowledge production in the social and human sciences is a way of constructing social life while trying to understand it, knowledge production is therefore a social construction or a way of acting in the world, which reflects particular ideologies, including the traditions of investigation within which researchers have been educated or which they have embraced.

In spite of the fact that, in many contemporary research circles in the social and human sciences, the Foucauldian position that “truth is of this world” (Foucault, 1979, p. 12) is a truism, and that researchers operate within “regimes of truth” (Foucault, 1979, p. 12), which legitimate specific particular procedures and practices, the equation of truth finding with knowledge production still guides much of the work done in these fields, including the area of applied linguistics (AL). This is so because, like any area of research in the social and human sciences, the field of AL borrowed the idea of research and the principles that guide such an endeavor from the positivistic perspectives of the natural sciences. Nevertheless, opposing the positivistic tradition, the interpretativist view is becoming more and more relevant in the area of AL, as will soon be shown. What is discussed here are the ideologies which underlie both research methodology traditions. It must be said that the issues involved in these particular “regimes of truth” are presented in a necessarily simplified manner. They involve much more complex issues in the philosophy and sociology of science than can actually be accounted for here. The aim is to draw as clear a picture about them as possible so that the underlying ideologies can be uncovered. Also, researchers in their practices will not necessarily fit either of those two positions neatly.

2 IDEOLOGY IN RESEARCH METHODOLOGY

Those two traditions reflect an old philosophical debate, which started out in antiquity: the nomothetic and the hermeneutic modes of inquiring about the world (Ochsner, 1979). This debate is related to two different views about whether the social world exists independently from our knowledge of it or not. In the nomothetic tradition, truth finding is constitutive of the research endeavor. As mentioned above, this tradition is what has been conventionally called positivistic research, that is, it has a deep concern with constructing new knowledge which is founded on the idea that the researcher is necessarily separated from the object of his or her investigation: a view which is contrary to the Foucauldian idea about truth. The positivistic position therefore characterizes what is thought of as value-free or ideology-free research.

Research is then constructed on the crucial principle that it is possible for the researcher to produce objective, replicable, and falsifiable knowledge. Statistics are therefore fundamental in determining the validity of findings since particular statistical tests which are adequate to specific research designs can demonstrate the significance level of results and can, so to speak, determine how truthful they are. This particular ideology as regards research methodology is still prevalent in a lot of what is called AL research due to the deep influence positivism has exerted across the academic world.

In this tradition, it is the observable experience of the fact that matters and such a position implies particular methodological procedures to approach the object under investigation. In the positivistic view, the social world variables have to be standardized and controlled and as such they can be statistically dealt with so that findings, resulting from inferential statistical tests, can be generalized to other contexts. "Reality," as it were, can be reduced to a cause and effect relationship, which becomes observable by means of standardization processes and through hypothesis testing in experimental research. What matters is objectivity since the social facts resist our will (Hughes, 1990). Obviously, the positivistic researcher is aware of the difficulties of constructing research designs which are value-free when dealing with human beings and social facts.

That is the reason why the investigation methodology includes procedures that try to account for this difficulty: manipulating variables, hiding a tape-recorder, concealing the research objective from the interviewee, and so forth, so that one can find "truth," so to speak, as it really is. However, as will be discussed below, "when the object of observation is human behavior the problem is endemic" (Cameron, Frazer, Harvey, Rampton, & Richardson, 1992, p. 7). Probably, because it is inspired in the natural sciences and, therefore, in the power they have traditionally had in research funding bodies, this view of research in many parts of the world is very frequently considered the legitimate manner of knowledge production or, in fact, what research entails. In AL, Hatch and Farhady (1982) well exemplifies the positivistic tradition.

Other researchers, nevertheless, have imagined research through an episteme that is conceptually very far from the kind of positivistic AL research methodology briefly mentioned above, although they are also interested in empirical findings. These researchers have been operating within an interpretativist framework in which it is impossible to separate the researcher from the object of his or her investigation. In fact, it is not desirable to do so. The nature of the investigation object in the social and human sciences is so different from that of the natural sciences that it does not make sense to use natural sciences research procedures in the social and human sciences. This is particularly relevant because researchers and their views of the world are understood as a constitutive part of the socially constructed research object under scrutiny.

The nature of the social world is of such complexity that it is necessary to discover adequate means and procedures to do research in the social and human sciences. What is specific to the social world is the fact that the meanings that characterize it are constructed by human beings, who interpret and reinterpret the social world around themselves or the

social object under investigation, constructing therefore not a single "reality" but several. That is to say that the fact that human beings are language users makes it inadequate to use natural sciences procedures to do research in the social and human sciences:

unlike physical phenomena, social actors give meaning to themselves, to others and to the social environments in which they live. They can describe what they do, explain and justify it, give reasons, declare their motives, decide upon appropriate courses of action, try to fit means to ends, and so on. (Hughes, 1990, p. 96)

That is to say, they themselves and the world in which they live are discursively and socially constructed. Research in this field has to account for the plurality of voices in action in the social world, and has to take into account that this fact involves issues related to ideology, power, history, and subjectivity. That is not to imply that positivistic research is ideology-free, since one cannot escape ideology in any discursive action, as pointed out above, but in the interpretativist research mode ideology is considered intrinsic to the research act. In this tradition, it is not possible to ignore participants' views of the social world to investigate it. On the contrary, these very views are what matters since the social world is believed to be constructed by human beings.

Instead of statistical findings resulting from inferential statistics, what is paramount in the interpretativist tradition are the meanings provided by different participants in the research operation, which can together provide a possible interpretation to what is being investigated. Instead of objectivity, the focus is on intersubjectivity. It is the participants' views that construct the social world, which depends on human beings for its existence. What characterizes the approach to what is being investigated is not the personal observable experience, but rather an indirect approach through the interpretation of the several meanings that constitute the research object, deriving from different research instruments (interviews, audio and video recordings, field notes, introspective protocols, and so forth), which allow for data triangulation.

In this tradition, generalization has to be understood from a different perspective since it does not derive from an observable cause. It is generalization that is constructed intersubjectively and that grants privilege to specificity, contingency, particularity, and situatedness. It is believed that it is impossible to control the variables, to use a positivistic category, which characterize human beings and the social world, so that one can demonstrate the cause of an observable fact. Standardization of variables is understood as constructing a distorted "reality," produced by the very investigation procedures that bring about research results. Such results are of no interest because they do not account for the multiplicity of meanings people attribute to the social world when they construct it.

What matters consequently is intersubjectivity: the meanings which we construct, disrupt, and reconstruct when we interact with one another. It is intersubjectivity that allows us to get closer to what we are investigating by comparing the meanings participants of the social world give to what is under scrutiny. The focus is on process features of the social world instead of on a standardized product, as in the positivistic mode. Ethnographic methodologies (van Lier, 1988; Rampton, 2006) can well exemplify this tradition in AL.

What has been contentious here in these two traditions are different coexisting paradigms that operate within distinct views of the world or ideologies: the possibility of separating human beings, their ideas, feelings, values, political positions, and so forth, from the act of doing research and, in fact, the desirability of doing so. Therefore, the two different kinds of metaknowledge discussed with respect to the research operation in AL imply different ideologies or produce different semantic effects.

Another insightful way of looking into these two research methodology ideologies is by comparing modernist and postmodernist theorizing. While modernist theories may be

equated with positivistic principles, it could be said that postmodernist theories may be related to the interpretativist position. Modernist research focuses on the construction of big generalizations or narratives which can explain what is going on in the world by appealing to totality, universality, homogeneity, and essentialism; therefore, statistical procedures that may collaborate with constructing big narratives by amassing a lot of statistical data and by ignoring qualitative aspects of the investigation make a lot of sense. Postmodernist theories, on the other hand, center on plurality, contingency, heterogeneity, and situatedness, which implies that what matters are the meanings and discourses that people resort to in order to live life in particular circumstances or contexts.

It is no wonder that what is of concern within postmodern theories is the construction of small narratives which help to explain life locally. This view is therefore well aligned with ethnographic principles, to keep to the research methodology mentioned above, since they provide methodological means to deal with particularity, situatedness, and local contingency, as well as with the social constructionist nature of social life. That is not to say, however, that interpretativist research is a corollary of the postmodernist theories that have recently shaken the humanities and the social sciences, since the interpretativist tradition is part of the old hermeneutic mode of inquiry which gained new strength in the 20th century long before postmodernist theories came about. However, because of its concern with particularity, locality, situatedness, and contingency, this type of research seems to capture the postmodernist view of the world as being constructed by discourse locally, here and now, rather than being explained in terms of cause-and-effect relationships that result from standardized variables and that allow for big narratives and generalizations, typical of a positivistic perspective.

The criticism that postmodernist theories have raised in connection with the so-called modernist view of the social subject as ahistorical, homogeneous, and essentialized, and therefore ignored, have also been crucial in attempting to redescribe who the subject of research in AL is. This trend has introduced the need to retheorize the subject in AL in terms of gender, sexuality, race, social class, and so forth, drawing attention, as a consequence, to the subject's heterogeneous, fragmented, and performative nature. These two issues may be thought of as the discursive and the somatic turns in AL.

For many contemporary applied linguists (Pennycook, 2001; Rampton, 2006; Moita-Lopes, 2006a), there is a need to retheorize AL in relation to recent social changes we are experiencing in society (e.g., reflexivity: Beck, Giddens, & Lash, 1994; time-space compression: Castells, 1999; fluidity: Bauman, 1992), which make the use of modernist theorizations of society and of our actions in them nonsensical or meaningless. Accordingly, modernist research ideologies have been questioned since they seem to be inadequate to account for such changes and for the necessity of redefining commonly used theoretical constructs in the field such as language (Makoni & Pennycook, 2006); identity (Moita-Lopes, 2006b); speech community (Rampton, 2006), for example. There is a demand for an AL which is tuned in with the zeitgeist of our times, which cuts across the humanities and the social sciences in general.

In particular, there is a concern, in many circles, with the development of an AL that aims at thinking beyond the given traditional epistemological limits of this field. Such an AL is specially interested in the production of "a narrative which changes the present," as the cultural theorist Venn (2000, p. 2) points out, or in the construction of alternatives for the present, based on the understanding that many of the narratives we were told about who we are or about what the world is like are in crisis or are being seriously questioned. This perspective purposefully blends in a concern with doing research and doing politics so that in the very research design the possibility of social reinvention or of considering new alternatives for our lives is directly dealt with: an issue which seems to be paramount in applied research. This point is particularly relevant if it is true, as

mentioned above, that “truth in the social sciences [and in the humanities] could be refigured in terms of regimes of truth and of instruments for instituting the particular forms of sociality which theory theorizes” (Venn, 2000, p. 4).

There is still a last point which emphasizes the need to see ideology as intrinsic to the research operation. This is an issue raised by the sociologist Boaventura de Sousa Santos (2001, p. 18): What happens to a world in which “‘reality’ seems to be definitely ahead of theory?” The contingency, the rapidity, and the unexpected events of contemporary life have shown that practice is more relevant than theory in our times or that “theory is practice under another name” (p. 19). Within these conditions, it is impossible to claim or to keep to an analytical or to a theoretical perspective. This position questions the difference between theory and practice: a very cherished dichotomy in the field of AL, which constituted one of its tenets for a long time, particularly because of its relationship with the positivist need of “critical distance” from the object of investigation.

If such a difference does not make any sense anymore, what is necessary is to say “no” to the ideal of “critical distance and acknowledge the necessity of continually searching for critical proximity” (Santos, 2001, p. 19): a vital concern in applied studies. Such proximity must go in the direction of those research participants situated in social practices in which researchers operate: a fundamental ethical issue. This is a point which is related to the question already raised that the researcher is intrinsically involved with the knowledge he or she produces: “knowing, being and desiring are seen to relay each other” (Venn, 2000, p. 15) in the act of knowledge production. Instead of placing AL on a very clear basis from which to work, this position emphasizes the need of thinking of research in this field as a problematizing practice (Pennycook, 2001), in which AL is understood as an area of investigation being continually reconstructed and anchored on unstable and movable grounds.

Iedema, Rick

THEO VAN LEEUWEN

Rick Iedema (1954–) is a discourse analyst and semiotician whose work in health communication, organization studies, and organizational semiotics has made important and innovative contributions to discourse analysis and social semiotics as well as to the fields with which his research has been primarily occupied. He has played a prominent role in introducing discourse analysis in organization studies and health communication, and continues to publish in international journals of discourse analysis as well as in medical journals and journals of organization studies. His earlier work, which used detailed linguistic and multimodal analysis to shed light on organizational interaction as well as on media discourse (Iedema, Feez, & White, 1995) and the construction of reality in documentary film (Iedema, 2001a) is still widely cited, and his concept of “resemiotization” (Iedema, 2001b) was highly influential in shifting the focus from textual analysis to the kind of combination of textual analysis and ethnographic observation that characterizes more recent work in social semiotics, such as the work of Kress and Jewitt (e.g., Kress et al., 2005). His later work became on the one hand increasingly interventionist and consultative, focusing on improving hospital communication, and thereby patient care, but also continued to develop his theoretical and methodological outlook, with an emphasis on combining the microanalysis of face-to-face interactions and documents with the macroanalysis of contemporary organizational practices; and on the aims and methods of discourse analysis in a time when stable organizational structures, resulting in predictable textual patterns, make place for instability and constant change, in organizational structures as well as in the discursive practices that realize them.

Iedema’s concept of resemiotization (Iedema, 2001b) is indebted to Bernstein’s concept of “recontextualization” (e.g., Bernstein, 1990) as well as to Bruno Latour’s account of the creation of facts in science (e.g., Latour, 1990), in which scientists’ intuitions transform into experimental practices which, in turn, transform into generalizations that acquire the status of facts. However, Iedema sees resemiotization as a textual practice that is fundamental in creating organization, a practice of “writing order to structure work” (2003a: 175). The discourses that structure organization, he argues, are first negotiated in face-to-face meetings, then resemiotized as authoritative written documents, and finally enshrined in work practices, or even in bricks and mortar. His study of the planning of a new health facility is a key example. Meetings between the architect planners, bureaucrats, and future users tentatively move toward a sense of agreement, in which some voices, and some interests may be marginalized or silenced. These are then transformed into written documents which are not only more formal and general but also more authoritative and non-negotiable than the spoken discourses which they resemiotize. Grammatical intricacy (e.g., “welfare workers working with students”) changes into lexical density (e.g., “student welfare workers”), qualifiers become classifiers and are no longer negotiable. And tentative formulations (e.g., “Um, but yes basically we do want it to be kept separately, so that eh the other patients don’t get sort of affected by people who were brought in”) become authoritative and imperative directives (“the patient admission area . . . needs to allow discrete transfer of patients”), and then architect drawings, which are even less negotiable, as by this time significant resources have been committed (Iedema, 2003a: 144). In this

way Iedema places the characteristic differences between speech and writing described by Halliday (1985) in their social and historical context, explaining them, rather than only describing them. As speech becomes writing, a “difficult set of interactions” changes into “an organizationally productive outcome: the architect planner has been able to produce a planning report with designs and a tender for the builders that got signed off by all stakeholders” (Halliday, 1985, p. 145).

The concept of resemiotization also includes broad changes in the semiotic landscape, for instance, the contemporary move towards visualizing things that were formerly done with words only (Iedema, 2003b). As an example, Iedema shows how Apple, in 1992, provided “getting started” instructions for the buyers of a new computer in the form of a booklet couched in imperative language, with bolded warnings (“**Important!**”), and with illustrations that visually elaborated written descriptions. By 1999, this had become a fold-out brochure in which description of the computer’s features was only visual, in which text and image were complementary rather than rephrasing each other, and in which the imperative nature of the writing was downgraded and the “importance” of warnings indicated by central location in the picture, rather than verbally. As in the case of the hospital-planning meeting, Iedema said, such resemiotizations should be studied as processes. Discourse analysis should have a historical dimension, even in the case of more long-range histories, such as the histories of genres (“resemiotization enables us to pose ‘supra-logogenetic’ questions about how documentaries or displays themselves come about as semiotic constructs through the deliberations of writers, filmmakers, planners and builders,” Iedema, 2003b, p. 49) or the history of writing itself, as Iedema shows in an overview of the history of writing as a history of organizational control (Iedema, 2003a, chap. 5). Finally, resemiotization often occurs simultaneously in different fields, along the lines of quite similar “schemes.” Abstract modernism, for instance, manifested itself not only in art, but also in magazine layout, home decoration, and so on (Iedema, 2003b, p. 44). This way of combining the “objective-analytical” analysis of semiotic artifacts or events with the—theoretically underpinned—study of their historical genesis is one of Iedema’s key contributions to social semiotics.

Iedema’s *Discourse of Post-Bureaucratic Organization* (2003a) is both the most complete statement of the earlier stage of his work, and the beginning of his later work. It underpins his approach to discourse analysis theoretically, methodologically, and historically, with a chapter on the history of organizational discourse from early Mesopotamian writing to Fordism and the recent “post-bureaucratic” turn away from a focus on the alignment and control of unruly workers to engagement, enthusiasm, and initiative as driving forces for inspiring workers and organizing the workplace. Along with an account of resemiotization, it discusses the “symbolic violence” which can occur in face-to-face meetings, as the voices and interests of less powerful participants are marginalized or silenced. And it contains an important account of medical record keeping and the consequences of replacing paper-based records with electronic patient care information systems, which change individual, case-based records with an “externally regulated scriptural regime” (Iedema, 2003a, p. 166) that forces clinical practitioners to use predetermined categories, functions to link different stakeholders together, even extra-locally, and allows “evaluation, calculation and intervention” (p. 150) on a hitherto impossible scale.

The concluding chapter of the book signals the second phase in Iedema’s work, a move away from a tradition of discovering stable regularities and patterns in texts, and from taking up an objective outsider’s stance, whether descriptive or critical, toward a “more volatile, political, confronting and involved” discourse analytical practice, which therefore “may not always translate into products that are amenable to accepted notions of academic purpose, output and identity” (Iedema, 2003a, p. 204). From here on Iedema focused on

large-scale research projects aiming not only at analysis and critique, but also at improving discursive practices that tend to be conducted in ways that bear risks for hospital patients, such as “handovers” between ambulance drivers and emergency doctors, the interactions and procedures relating to dying patients in intensive care units, and the open (honest) disclosure of “adverse events,” for instance to the family of patients who have died as the result of such events. While continuing to focus on organization and communication, the question is now one of how the organization and communication of clinical work impacts on patients’ safety and well-being, and also, increasingly, on the role of affect, both in internal communication, for instance in teams, and in the communication between clinicians or other hospital representatives and patients.

In this work Iedema’s approach to discourse analysis changes, and no longer aims at discovering patterns and regularities, for instance the generic structure and use of language in paper-based medical records, but at finding “non-obvious traces” (Iedema & Scheeres, 2009). In an unstable environment, characterized by constant change, what matters, Iedema argues, is not to look for stable patterns, but to look for tensions that may either give rise to new solutions, or turn out to be symptomatic of problematic issues that need to be addressed. In other work, for example, the work on open disclosure, his research is primarily based on a thematic, rather than a linguistic or generic analysis of interviews with patients, supplemented with questionnaires, from which principles for improved disclosure are then extrapolated (Iedema et al., 2010). In yet other work (Iedema, Long, Carroll, & Lee, 2006), the researcher becomes a “video ethnographer,” who records the everyday practices of clinicians and then engages them in a process of video reflexivity which allows potentially problematic processes that have become invisible as a result of habitualization to become visible, discussable, and open to change. A striking example is the story of a nurse who “was used to spend hours on the ward with a clipboard to rate clinician compliance with rigid personal-protective equipment and hand-washing rules,” but now, in the video record of her everyday environment, saw “footage of clinicians examining patients’ wounds and then leaning on the bed rail, transferring potentially infectious material to a place where other people could pick it up and carry it further again” (Iedema & Carroll, 2010, p. 74). In work of this kind, research is on the one hand “subjugated to the needs of practitioners,” and yet also remains “based on well-established theoretical principles” (Iedema & Carroll, 2010, p. 73). Researchers engage clinicians in a dialogue that leads to common understandings and insights, and to changed practices. While recognizing the influence of Fairclough (1995), who first moved critical discourse analysis into the area of corporate culture and organizational discourse and first linked discourse analysis with social theory, Iedema distances himself here from the kind of critical discourse analysis that interprets and critiques institutional texts but does not lead to close engagement with the institutions and practices it criticizes or to developing strategies for change, and that does not acknowledge positive aspects of the new work order, such as worker involvement and increased accountability.

In this new work, Iedema acknowledges the need to “recognize the relativity in situated practice, including their own,” and explicitly problematizes the balance between engagement and distance that is needed for self-reflexivity. But, while in earlier work (Iedema, 2003b), he uses close textual analysis, for instance, to criticize a television documentary for its selective focus on patients and doctors, and for backgrounding and marginalizing the point of view of hospital administrators, he now argues that the selectivity of the camera can be overcome by negotiation over “what to film, what footage to screen back, how to see the footage and what conclusions to draw from it” (Iedema & Carroll, 2010, p. 76), and moves away from the balance between text analysis and ethnography that can be found in other social semiotic work, such as the education research by Kress and his

associates (e.g., Kress et al., 2005). Iedema is well aware that his radically engaged approach to research may invite critique, but adamant that “the relativization and historization of practices, identities, knowledges and values” must go together with “the building of solidary relationships through transformation” (Kress et al., 2005):

No doubt, the paradigm presented here challenges discourse analytical conventions much as it upsets social scientific expectations about appropriate methodologies, authoritative findings and generalizable outcomes. But if discourse analysis is to have relevance in the contemporary world, it will only do so if it can capitalize on its most significant achievements: the relativization and historization of practices, identities, knowledges and values, and the building of solidary relationships through transformation. (Iedema & Carroll, 2010, p. 82)

Imaginary Words

PAUL MEARA

Imaginary words—sometimes also called pseudo-words, nonsense words, or nonce words—are strings of letters which resemble real words but do not actually exist as words in a specific language. Thus, ‘shern’ is a plausible letter string for English, but does not appear as a word in any of the standard dictionaries.

Imaginary words have been used in a number of experimental methodologies in applied linguistics, notably in yes/no vocabulary tests, in tests of inferring the meaning of unknown words, and in tests of short-term memory skills in L2 learners (Meara & Jones, 1990; Beeckmans, Eyckmans, Janssens, Dufranne, & Van de Velde, 2001; Mochida & Harrington, 2006). Imaginary words are also sometimes used in psycholinguistic studies of word recognition, principally in lexical decision tasks. The discussion that follows will illustrate some of the factors affecting the construction of imaginary words in English, and some problems that arise when they are used as stimuli in experimental studies. The broad lines of the argument apply not just to English, but *mutatis mutandis* to other languages as well. There are, however, some special considerations that apply in languages which have more restrictions on their word structure than English does.

Imaginary words used in psycholinguistic studies need to be carefully constructed so that they do actually conform to the orthographic and phonological rules of the relevant language. Orthographic rules are generally easy to state: ‘lbonk’, for instance, is not an acceptable imaginary word in English because English does not allow lb- clusters in word initial position. Similarly, ‘blijnd’ is not an acceptable imaginary word in English because English does not code vowels with this letter sequence—in fact it does not allow -ij in any position. Likewise, English does not allow -yc or -tn in word final position, so these constraints would rule out imaginary words like ‘headyc’ or ‘thatn’. The interaction between phonological considerations and orthographic ones are sometimes more difficult to deal with, and some important statistical patterns make possible words in English very unlikely. ‘Klutt’, for example, is a possible English word, but an improbable one: few English words begin with kl- and few end with -tt. The combination makes ‘klutt’ very easy to identify as an imaginary word.

In some of the early psycholinguistic studies in English, researchers adopted a somewhat cavalier attitude toward these rules, and assumed that it was sufficient to change a single letter in a real word to generate an acceptable imaginary word. Thus, ‘book’ might generate ‘kook’ by changing the initial ‘b’ for a ‘k’, ‘crook’ might generate ‘clook’ by changing the ‘r’ for an ‘l’, or ‘cook’ might generate ‘couk’ by exchanging an ‘o’ for a ‘u’. This approach, though still widely used, is only partially successful. Changing single letters randomly fails to respect the distribution of letters in real words—swapping a ‘t’ for a ‘j’ or ‘k’ in any word is unlikely to produce an imaginary word which looks convincing. Typically this procedure produces forms which bear a superficial resemblance to English words, but differ from real words in subtle ways. In the example above, ‘kook’ is only marginally acceptable as an imaginary word. ‘K’ is relatively infrequent in English words, so a word which contains two ‘k’s stands out. English also seems to have a preference for monosyllabic words not beginning and ending with the same consonant, and words with these characteristics are phonologically marked. Taken together these two features mean that

2 IMAGINARY WORDS

'kook' deviates quite significantly from the norm of what an English word should look like, even though it is technically a possible word. Similar arguments apply to 'couk'—there are plenty of English words that begin with cou-, but they are all pronounced [kau] rather than [ku], and only a handful of them are monosyllables. 'Clook' is the best of these three items, but even this form is statistically unusual, as there are no real words in English that end in -look apart from 'look' itself.

A further problem with the change-one-letter approach is that not all positions within a word are equal, and they have different effects on readers. Letters at the beginning of a word seem to be much more salient than letters in the interior of a word. Altered letters within a word are often not noticed by readers, whereas they will often fail to recognize the original form of a word where an initial letter has been altered. Changes at the ends of words tend to be salient because the endings of words tend to be more regular and predictable than other segments. Changes here will stand out because they are statistically unusual.

Particular problems arise when we try to construct imaginary words that are longer than the examples above. Changing a single letter in a long word hardly ever produces a wholly acceptable imaginary word—'aliphant', 'elethant', and 'elephant' are all orthographically plausible in English, but readers tend to see them as variants or misspellings of 'elephant', rather than words in their own right.

Longer words also present problems because of morphological constraints. In English, it is possible to construct imaginary words by combining morphemes that do not normally appear together. For example, 'infradiction', combining infra- as in 'infrared' and -diction as in 'contradiction', seems to work, as does 'megamatic', combining mega- as in 'megaton' with -matic as in 'automatic'. Again, however, some care needs to be taken in combining morphemes which can be interpreted, even though they do not actually exist in common usage. 'Pyrostasis' probably does not exist as a word in English, but if it did, it would probably mean something to do with 'fire' and 'stability'. Pyro- is a Greek morpheme for fire, and -stasis is also a Greek morpheme meaning stability. Putting these two morphemes together gives you a form which is interpretable at some level by anyone who is at least passingly familiar with the way learned words are constructed in English. This is very different from the examples that we considered in the previous paragraph, where 'clook' provides no clues as to its meaning. One could argue that an advanced learner who claims to know the meaning of 'clook' is just wrong, but an advanced learner who claims to know the meaning of 'pyrostasis' is actually demonstrating some high-level knowledge of the way English morphology works. This suggests that data based on readings of imaginary words need to be treated with some caution.

A particular problem with using imaginary words with L2 speakers is that these subjects will often misread these items as real words that they know already. 'Leddy', for example, looks like a good imaginary word, but is sometimes read by L1 French speakers as 'lady', a high-frequency familiar form. Some particularly complex issues arise when we use imaginary words with speakers whose L1 stresses the consonant structure of words. Arabic is a good example of this. L1 Arabic speakers tend to confuse words like 'mountain' and 'maintain' and 'mention'. These subjects might be expected to react to imaginary word forms like 'moonten' or 'monteen' in a way that you would not expect to find in L1 speakers of French or German. In fact, the use of imaginary words as stimuli in experiments is more problematical than it looks at first sight.

Consider an experiment in which subjects are asked to read an L2 text and infer the meaning of a number of unknown words. A common practice here is to select a reading passage and to replace a number of real words with a set of imaginary words. This is generally done to ensure that none of the subjects being tested knows any of the target words. Thus, we might replace the form 'elephant' in the sentence *The elephant used its*

trunk to pull the bananas from the tree with ‘aploquom’, giving us *The aploquom used its trunk to pull the bananas from the tree*. Subjects are then required to infer the meaning of ‘aploquom’. Assuming that the subject is familiar with elephants, there are two possible scenarios that we have to deal with. One scenario is that the subject doesn’t know the word for ‘elephant’ in English, but can identify from the text that this is the intended meaning. This subject then infers that ‘aploquom’ might mean ‘elephant’. This seems like a straightforward case of lexical inferencing—though it raises some awkward ethical issues about whether it is appropriate to teach subjects words that do not mean what they think they mean. The second scenario is that the subject already knows that ‘elephant’ is the name for this animal in English, and assumes therefore that ‘aploquom’ means something else. It could be the name of another animal with a trunk that likes bananas (some kind of monkey with an extended proboscis, perhaps), or it could be a special kind of elephant, but this raises the question of how ‘aploquoms’ differ from ordinary ‘elephants’. This second case is clearly not a straightforward example of lexical inferencing.

In general, experimenters often assume that these imaginary words have no specific meaning, but this does not necessarily mean that they are not meaningful in other senses. In the case of ‘pyrostasis’, we have already seen that words with meaningful parts can sometimes have an implicit meaning that can be computed on the fly. It is often possible to assign imaginary words to specific parts of speech because of their morphology: ‘migrate’ for example looks like it might be a verb, ‘fluctual’ looks like an adjective, and ‘banderage’ is probably a noun. Beyond this, some imaginary words are typically judged by native speakers to be more meaningful than others—largely because of their resemblance to other real words. Thus, real words in English beginning with gl- and a front vowel tend to

4 IMAGINARY WORDS

be associated with light, whereas real words beginning with gl- and a back vowel tend to be associated with dark. We might expect imaginary words with these characteristics to have similar associations.

Table 1 provides a short list of imaginary words which address some of these issues. The items in this table are all names culled from the UK telephone directory. This provides a check that the item is indeed an acceptable form in English, and generally meets the phonotactic constraints of English (see also The Irvine Phonotactic Online Dictionary at www.iphod.com). The items do not have a commonly accepted meaning, though they may be familiar to some readers in the sense that they know a person with this particular name. For example, 'heseltine' was a minister in Mrs. Thatcher's government. This makes the form familiar to some people, and it may have some associations for readers who are aware of Heseltine's political views. It does not have any intrinsic meaning however. This property makes items of this sort good candidates for stimuli in experimental studies. Note, though, that using proper names will not work in other languages where naming conventions are stricter than they are in English.

In summary, imaginary words play a useful role in applied linguistic research, but their use is not always as straightforward as it seems at first glance, and some care is needed in the interpretation of research which uses them extensively.

Immersion Education

ROY LYSTER AND FRED GENESEE

Immersion is a form of bilingual education that provides students with a sheltered classroom environment in which they receive at least half of their subject-matter instruction through the medium of a language that they are learning as a second, foreign, heritage, or indigenous language (L2). In addition, immersion students receive some instruction through the medium of a shared primary language, which normally has majority status in the community. School contexts where individual minority language students find themselves without any first language (L1) support and with a majority of native speakers of the target language do not qualify as immersion programs and are instead regarded as “submersion” classrooms. Immersion education and “content and language integrated learning” programs known as CLIL (see Mehisto, Marsh, & Frigols, 2008) can be regarded as similar variants of bilingual education insofar as CLIL, like immersion, aims to integrate content and language instruction. In practice, immersion programs include a wide range of languages, whereas English is the predominant L2 in CLIL programs. As well, while immersion programs view academic achievement and language development as equally important, CLIL programs can vary with respect to how much emphasis they place on acquisition of academic content through the L2.

Alternative models of immersion differ with respect to the grade level when the L2 is used for academic instruction, amount of instructional time taught using the L2, and the number of grades when academic subjects are taught in the L2. One can distinguish *early immersion* (beginning in kindergarten or grade 1) from *delayed* or *middle immersion* (beginning in grade 4 or 5) and *late immersion* (beginning in grade 7, or the initial grades of secondary school). Programs also differ with respect to the amount of instruction through the L2—in *early partial immersion* programs, only 50% of instruction is ever taught in the L2; in *total immersion programs*, all instruction for one or more grades is through the L2. Notwithstanding such variation, most immersion programs aim for (a) advanced levels of functional proficiency in written and oral forms of the L2, (b) normal levels of L1 development, (c) grade-appropriate levels of achievement in academic subjects, and (d) cultural pluralism through increased intercultural competence. An additional goal in many contexts is to promote active use of the target language beyond the classroom.

Immersion programs have been instituted in countries around the world for a variety of reasons. Some of these reasons are to promote national policies of bilingualism and multilingualism (e.g., French immersion in Canada, Swedish immersion in Finland, and Basque, Catalan, and Valencian immersion in Spain), national languages in countries with large populations of students who do not speak the national language (e.g., Estonian immersion for Russian-speaking students in Estonia), proficiency in important regional, world, or heritage languages (e.g., English immersion in Japan, Hebrew immersion in Canada), and the survival of languages at risk of extinction (e.g., Mohawk in Quebec).

Research has found that immersion students attain the same levels of achievement in all aspects of the L1 as students attending non-immersion programs, although they may experience short-term lags in literacy development during grades when the L2 is used as the exclusive language of instruction. They also demonstrate the same levels of achievement in academic domains as students in non-immersion programs. Likewise, immersion

students attain advanced levels of functional proficiency in written and oral aspects of the L2 that is significantly superior to that of students who receive traditional L2 instruction for short periods each day. Their comprehension skills are generally greater than their production skills. Immersion students with more exposure to the L2 tend to achieve higher levels of L2 proficiency than students with less exposure whereas there is little, if any, difference in L1 achievement among students in different program models. In other words, more and earlier exposure to the L1 does not guarantee higher levels of achievement than less or later exposure to the L1. Evaluations have also shown that immersion programs are suitable for students with a wide range of background characteristics, including students with typologically similar (e.g., French and English) and dissimilar L1s and L2s (e.g., Japanese and English), students from different socioeconomic backgrounds, students with different levels of academic ability, and minority as well as majority cultural group students.

Second Language Development

Despite their impressive functional L2 proficiency, immersion students do not attain native-like expressive language skills, even after 10 to 11 years in the program. More specifically, L2 usage is often marked by lexical and syntactic transfer from the L1, restricted vocabulary and simplified grammar, and is non-idiomatic (e.g., Harley, 1992). In a large-scale study of the L2 proficiency of French immersion students in Canada (Harley, Cummins, Swain, & Allen, 1990), immersion students, in comparison to native speakers of French of the same age (i.e., 11–12 years old), performed as well on measures of discourse competence, but were clearly less proficient on many aspects of grammar, and especially with respect to verbs. They also performed significantly differently on all sociolinguistic measures. These findings have led to discussions of and research on whether the primary focus on content that characterizes immersion is necessarily the most effective way to promote L2 proficiency.

These shortcomings in L2 proficiency can be linked to initial conceptualizations of immersion pedagogy, which are now thought to have underestimated the extent to which the target language needs to be attended to. Many researchers now concur that for immersion and other content-based approaches to be effective, the instruction must be language-rich and discourse-rich. One way to include a greater focus on language in immersion is through form-focused instruction, which includes pedagogical techniques that draw learners' attention to form–function relationships in the target language (e.g., Spada, 1997). Form-focused instruction is usually embedded in meaningful tasks and, thus, differs in consequential ways from traditional grammar lessons that emphasize memorization of forms out of context. The distinction between form-focused and traditional grammar instruction is important in discussions of immersion pedagogy because, in spite of claims that immersion education entails language learning through content alone without any accompanying L2 instruction, a considerable amount of traditional grammar instruction has been observed in immersion classrooms, but with indeterminate effectiveness (see Swain, 1996).

In contrast, a series of quasi-experimental studies conducted in French immersion classrooms yielded variable but, overall, positive results for form-focused instruction designed to target linguistic features known to be problematic for L2 learners of French: perfective and imperfective aspectual distinctions (Harley, 1989), conditional mood (Day & Shapson, 1991), second-person pronouns (Lyster, 1994), and grammatical gender (Harley, 1998; Lyster, 2004a). In a review of these studies, Lyster (2004b) found that the most effective instructional treatments were those that were more form-oriented than meaning-oriented. Meaning-oriented tasks, such as the creation of childhood albums and the design of futuristic space colonies, were found to be similar to other types of content-based activities

routinely encountered in immersion and, thus, were less effective at changing students' use of accessible and recalcitrant interlanguage forms than were form-oriented activities designed to draw attention to the structural properties of target forms in the context of role plays or language games.

Research into immersion pedagogy (e.g., Allen, Swain, Harley, & Cummins, 1990) calls for a less incidental and more systematic instructional approach to ensure continued language growth in the case of lexical and grammatical development alike, yet with necessary differences between vocabulary and grammar instruction. A less incidental approach to vocabulary instruction is called for that goes beyond techniques that only facilitate comprehension and that also includes those that develop awareness of the structural and generative properties of words. In the case of grammar instruction, a more focused approach is also warranted, but with less decontextualized analysis of the target language in terms of its structural parts, and more systematic reference to form/meaning mappings in the target language during meaningful interaction and content-based instruction. The need for somewhat different approaches is called for in light of what teachers are currently doing as a result of the overriding nature of content-based instruction. That is, because much content instruction is lexically oriented, teachers are naturally inclined to focus on vocabulary more for the purpose of comprehension than for drawing explicit attention to the formal and generative properties of words. At the same time, because content instruction and its lexical orientation do not readily bring grammatical issues to the forefront, teachers are more inclined to do so either incidentally or in a decontextualized manner. Yet, for students to be in a better position to reap the benefits of learning their L2 through content, researchers recommend less teaching of the formal properties of grammar out of context (e.g., memorizing verb paradigms and parsing sentences) and more attention to form–meaning connections in the context of content-based instruction.

A counterbalanced approach to immersion pedagogy integrates both form-focused and content-based instruction across the curriculum in complementary ways that interweave opportunities for instructional input, student production, and classroom interaction. In terms of instructional input, immersion teachers can draw on a gamut of techniques that range from those designed to facilitate comprehension of subject matter to those designed to make language features more salient through noticing and awareness activities. In terms of student production, immersion teachers need to ensure a range of opportunities that vary from content-based tasks designed to promote the use of the target language for academic purposes, to practice activities designed to promote the proceduralization of target language forms that tend otherwise to be avoided, misused, or unnoticed. In terms of classroom interaction, teachers have a range of instructional techniques at their disposal that vary from the use of implicit feedback, such as recasts that scaffold interaction in ways that facilitate students' participation, to feedback in the form of prompts and other signals that push learners beyond their use of recalcitrant interlanguage forms.

At-Risk Students: The Case of Reading Acquisition

Despite evidence of the success of immersion for students in general, there is ongoing discussion of the suitability of immersion for students who face academic difficulties (e.g., Genesee, 2007). In fact, there has been little investigation of individual differences in achievement among immersion students and, in particular, students who experience academic difficulties related to reading. Competence in reading is critical for academic success, especially beyond the primary grades when students are expected to master increasingly complex and abstract academic subject matter and skills presented through written text. Reading is equally important in immersion. Despite the overall success of immersion

students with respect to reading achievement, there is a high rate of attrition from immersion programs due, in part at least, to reading difficulty (e.g., Obadia & Thériault, 1997), but we have little understanding of why some immersion students struggle when learning to read. Understanding individual differences in reading achievement is critical for determining the suitability of immersion for students who might experience academic difficulty because of reading difficulties and, as a result, withdraw from the program. A better understanding of reading achievement among immersion students, especially in the primary grades, would make it possible for early identification of those at risk for reading difficulties and for planning differentiated instruction that could eliminate or at least reduce the academic challenges they face as a result of reading difficulties. Research on monolingual students has shown that early identification and early targeted intervention can maximize response to intervention and help prevent reading difficulties altogether (e.g., Scanlon, Gelzheiser, Vellutino, Schatschneider, & Sweeney, 2008). These issues are particularly important in communities, such as Quebec and Estonia, where the target language is critical for communication in the larger community.

Research conducted in Canada on students in early French immersion programs indicates that students who experience difficulty learning to read in immersion are also likely to experience difficulties in a non-immersion program (Genesee & Jared, 2008; Erdos, Genesee, Savage, & Haigh, 2011). This research has also expanded our understanding of struggling L2 readers in ways that are useful for classroom practice. To be specific, a critical component of learning to read is word decoding and, not surprisingly, the most prevalent difficulty faced by students with reading difficulty, either with respect to single word reading or text reading, is decoding. It has been found that struggling L2 readers, like struggling L1 readers, have particularly poor phonological awareness skills and letter-sound knowledge which, in turn, are correlated with poor decoding skills (August & Shanahan, 2006; Erdos et al., in press). Research has also shown that the word-reading skills of struggling L2 readers, like those of struggling L1 readers, improve significantly following explicit phonics and phonological awareness instruction. Moreover, students with good phonological awareness skills and letter-sound knowledge in the L1 also have good phonological awareness and letter-sound knowledge in the L2. In fact, the phonological awareness skills and letter-sound knowledge of kindergarten students in their L1 can predict their L2 phonological awareness, letter-sound knowledge, and decoding skills up to three years later (Erdos et al., 2011). It is likely that the magnitude of these correlations is related to the similarity between the two languages (French and English in the case of these studies), and smaller crosslinguistic correlations might be found in the case of typologically different languages, such as English and Chinese, or English and Hebrew, for example.

Although less extensive, the available evidence on reading comprehension indicates that reading comprehension difficulties in an L2 are similar to those experienced by L1 readers (Bishop & Snowling, 2004; Erdos et al., 2011). Both types of struggling readers have poor decoding skills. They also have weaknesses related to oral language, including both semantic and syntactic aspects of language, underlining the importance, noted earlier, of optimizing the oral language development of immersion students. This is especially important during the early grades in order to enhance reading comprehension skills and academic achievement later on. Considerably more research is needed into this aspect of reading in order to specify with certainty the exact nature of the language weaknesses of struggling readers.

The above findings have important implications for educational policy and practice. From a policy point of view, they argue for policies that are inclusive; that is to say, policies that do not preclude or discourage students who face academic difficulties related to reading from participation in immersion. Such policies are also recommended on the grounds

that the components of reading that pose difficulties for struggling L2 readers (i.e., phonological awareness and letter-sound knowledge for decoding along with oral language competence for text comprehension) are fundamental components of learning to read that all learners must master. Moreover, teaching such skills falls within the purview of classroom instruction. Addressing the needs of struggling L2 readers within the context of classroom instruction is a matter of planning differentiated instruction that reflects individual students' strengths and needs with respect to the critical foundation skills that underpin reading (i.e., phonological awareness, letter-sound knowledge, and oral language competence). Individual students' strengths and weaknesses can be assessed in the L1, before students have acquired proficiency in the L2, because of the strong crosslinguistic correlations that have been found. In this way, it is possible to identify and provide individualized intervention for students who are at risk for reading difficulty early on in immersion.

Once identified, immersion students who demonstrate persistent difficulty or failure to master the targeted skills (especially the foundational skills of phonological awareness and letter-sound knowledge) despite individualized instruction would then be recommended to a learning or reading specialist who, following appropriate further assessment, would provide more individualized, extended intervention. Such students might, in fact, have a specific reading impairment which would qualify them for specialist services in some educational districts. Another important implication of reading research findings for immersion classrooms is the importance of planning systematically, as noted earlier, for early oral language development that will support literacy and academic achievement in the higher grades. Thus, a comprehensive approach to early reading instruction in immersion, one that aims to meet the needs of all students, should include a focus on language proficiency along with a focus on the foundational skills that support reading acquisition.

Conclusions

Extensive research has shown that L2 immersion programs in their varied forms are effective in achieving advanced levels of functional proficiency in an L2. At the same time, participation in immersion does not jeopardize students' L1 development or academic achievement despite the fact that students receive less language and academic instruction in the L1 than students in non-immersion programs. While the overall content-based approach which is the hallmark of immersion has proven effective in developing high levels of communicative ability, ongoing research has highlighted the advantages of pedagogical interventions that integrate a greater focus on language into subject-matter instruction. Research on individual differences in L2 reading acquisition indicates that struggling readers in immersion are likely to experience the same difficulties in a non-immersion program and, moreover, that the difficulties they face entail the same foundational skills that all students must master in order to read with fluency and accuracy. With its variations in grade-level entry point, target languages, and academic subjects associated with each target language, immersion education is a flexible form of bilingual education. It will continue to evolve as it incorporates relevant research findings about effective instructional practices and develops differentiated instruction to respond to individual learners' needs in increasingly diverse student populations.

Immersion Programs

SIV BJÖRKLUND

Language Immersion

As a term, *immersion education* can be traced back to the 1960s and to Canada, where a new, intensive language education program model showed that young majority English speakers gained functional mastery of a new language in a French immersion program at no cost to their first language development (Lambert & Tucker, 1972). Since then, the immersion method of learning a language among students who mostly have no personal regular bilingual family contacts to fall back upon has awakened worldwide interest. Consequently, language immersion is used today as an umbrella term for many types of bilingual programs in a variety of linguistic environments. Sometimes the term immersion is misused for transitional bilingual programs which aim at assimilating speakers of minority languages to a dominant majority-speaker community (i.e., submersion). In some contexts there is also a certain skeptical wariness toward the indiscriminant use of the term, since the definition of majority and minority status of the languages involved is vital for the definition of immersion. Immersion is thus easily entangled with subtle emotional and attitudinal comeanings associated with language-policy strategies.

Essential Features of Immersion

Though immersion programs can be designed somewhat differently, there are essential features which identify them as programmatic language immersion.

First, immersion education programs are defined as additive programs which offer bilingual enrichment to their students. At the start of the program, students are mostly monolingual or have only limited skills in the immersion language. The development of the first language of the students will be at no risk even if the immersion language is extensively used as the medium of instruction during the students' school day. Today most immersion programs are set up as *second language immersion programs* (e.g., French immersion in Canada, Welsh immersion in Great Britain, Swedish immersion in Finland) because a major consideration is the local/regional people's perception of the necessity and benefit of being able to use two languages in daily life, for example, in the job market. In this case, immersion arises from outside school and the perceived need from the surrounding bilingual society to improve language learning in school. By contrast, in *foreign-language immersion programs* (e.g., English immersion in Hong Kong) the motivation for immersion often comes from a wish to move away from existing language-learning praxis in schools and to offer students more efficient tools to function in a more global and hence increasingly multilingual future. In this case immersion arises from within the school system and the perceived need to improve language learning in order to meet future challenges.

Second, to be defined as immersion, the immersion language must be used as the medium of instruction for a number of different subjects; that is, academic content is used as a vehicle for teaching and learning the language. To fulfill this vital feature of immersion, some minimum criteria for both the intensity of exposure to the immersion language

2 IMMERSION PROGRAMS

and the duration of the provision must be met. With regard to intensity, Genesee (2004) mentions that the criterion for this is “at least 50% of the prescribed non-language-related curriculum of studies for one or more years” (p. 549). Regarding duration, virtually all well-known and well-established immersion programs are program-based, running for several years and with a holistic long-term design. This extensive exposure and long duration puts immersion education in the position of being the most content-driven program in a categorization of programmatic levels of integrating content (Met, 1998). In the end, then, any immersion program takes into account the time devoted for each language within and between different subjects over a number of years, as well as instruction time in the immersion language, on the one hand, and in the first language, on the other. The same long-term and holistic approach is not automatically applied within a typical content-based instruction (CBI) or content and language integrated learning (CLIL) provision. Yet, CLIL, which has become a central content-based programmatic goal in a recent framework strategy developed by the European Commission (2005), is often confused with the term immersion. In particular, in Europe, CLIL is under strong development but today generally comprises only one or two content subjects (e.g., social sciences, mathematics) and therefore may include minimally only one subject teacher with linguistic competence in the language used as medium of instruction in that specific subject. Furthermore, it affects the individual student’s school day differently, since in CLIL students can only be surrounded by the language to be learned for a small part of the school day. By contrast, immersion students will spend approximately half to the whole of their school day surrounded by that language. Furthermore, in order to be successful in immersion, teachers must be open to innovative strategies (see e.g., Met, 1998), since there is no escape to a strict division between language and subject teaching.

Third, immersion programs were originally developed for monolingual majority speakers who have a strong support for their first language in the surrounding society. Therefore, most immersion classes are linguistically homogeneous (monolingual classes of majority speakers). Nevertheless, geographically varying linguistic conditions can be taken into account in the establishment of programs. In some contexts, the balance between a majority and a minority language is defined regionally, not nationally. In areas with endangered minority languages, immersion programs in some cases offer an opportunity to promote minority language and culture for both majority and minority students. In this case, the ratio of majority and minority speakers is balanced in order to get an optimal language program for each individual student. For example, we now know from results from Welsh and Irish immersion programs that a greater portion of minority speakers is essential for successful individual bilingual development when the immersion language is a threatened minority language. Yet another example of varying linguistic conditions is the United States, where the characteristics of *one-way* immersion programs are similar to the above-mentioned original immersion classes (consisting of only majority speakers), whereas in *two-way* immersion (or *dual immersion*) programs, both majority and minority language speakers with dominance in their first language and home support for this language are grouped together (e.g., see Lindholm-Leary, 2001).

Fourth, immersion is principally open to all students. This optionality can itself potentially function as a self-selection criterion; that is, only motivated parents or students choose an immersion program. Furthermore, as immersion is in particular developed for bilingual enrichment for students in a majority context, it is sometimes referred to as a prestigious or self-selective program with motivated students (see, e.g., de Meija, 2002). Nevertheless, results obtained within immersion programs clearly show that immersion can be beneficial for many kinds of students, and it has proven to be effective even for students who are predicted to be low achievers at school. Several studies have been carried out involving students with special needs and students at risk. For example, research results from

immersion in Catalonia (Artigal, 1991) have shown that when immersion attracts students from lower socioeconomic backgrounds, they get the same positive results as reported for other immersion programs. Since the individual factors, needs, and pedagogical strategies related to these student populations in immersion (and elsewhere) are extremely diverse, generalizations are still too imprecise and more studies are needed. The tendency is, however, that even if some students in immersion exhibit limited cognitive or linguistic capacity, they learn to use the immersion language, which is an enriching experience and an advantage for any student living in a bilingual local milieu (e.g., Laurén, 2006). In addition, teaching strategies and strategies for efficient classroom work have been identified and are constantly being scrutinized and refined within immersion (see Snow, 1987; Swain, 1988; Cummins, 1998; Met, 1998; Lyster, 2007). These strategies seem to be crucial not only for developing efficient immersion programs but also for helping students who run the risk of underachievement.

Results of Immersion

Ever since the advent of immersion programs, the design of immersion has involved a holistic evaluation component. These evaluations have always combined a focus on second language development with a thorough assessment of first language development, in addition to evaluation of overall content achievement. All in all, no other language education program has been scientifically evaluated to the same extent as immersion. Because typically the immersion curriculum is the same as the local/regional/national curriculum where the immersion program is implemented, meaningful comparisons are possible. This is typical not only of the first Canadian immersion programs but of other immersion programs all over the world.

Results have consistently shown that immersion students' ultimate attainment in their first language development and content development equal that of non-immersion students. In fact, immersion research results tend to point in the direction of the same positive effects on intellectual and linguistic progress as is the case with other balanced bilingual individuals (for cognitive benefits of bilingualism see Cummins, 1984; Genesee, Lindholm-Leary, Saunders & Christian 2006; Bialystok 2007).

Throughout the history of immersion evaluation, special attention has also been paid to the second language outcomes of the students, since this is the main reason for the establishment of immersion programs. Same-age native speakers of students' immersion language are often used as comparative reference groups, which clearly shows the high expectations set up for immersion education. Generally, receptive skills are described as being at near-native levels by the end of the program, and productive skills are reported to be more varied and seemingly dependent on many factors, such as students' active use of the immersion language not only inside but also outside the school milieu, pedagogy in the classroom, and attitudes and motivation of individual immersion students.

Motivation and Multilingualism as Orientations Within Future Immersion

In the original Canadian context, three main program alternatives linked to the students' age at the outset of immersion have been developed (*early*, *middle* and *late* immersion); within these alternatives, the intensity of exposure varies between *total/full* immersion and *partial* immersion. In Canada as well as in many European countries, early immersion programs are the most common variants, whereas in other countries (e.g., Australia) late immersion programs have become very popular.

4 IMMERSION PROGRAMS

In many immersion programs motivation forms a crucial factor affecting enrollment. Even though all immersion programs are enrichment bilingual programs, there are different reasons to participate in immersion. For example, programs in Canada and Finland are mainly established to enhance and make more efficient use of the official bilingualism of the country. Consequently, the motivation of immersion students and parents to enroll their children in immersion tends to be more instrumental, as good knowledge of the immersion language is useful for future career opportunities and suchlike. Other immersion programs are more oriented toward language maintenance (e.g., immersion in the Basque country, Catalonia, Wales, and Ireland) and language revitalization (indigenous language immersion programs, e.g., Hawaiian immersion). Even though the cultural component is a natural part of immersion teaching in all variants of immersion, it becomes more accentuated in the language maintenance or revitalization immersion programs, as the motivation to enroll is more integrative, and knowledge of the culture is equally important as (or even more important than) immersion language skills.

Immersion began as a language education program in which one immersion language was the focus of attention. However, there are today multiple-language immersion programs. In *double immersion* (e.g., in Canada; see Genesee, 1998), two immersion languages are used as media of instruction in content teaching. During the first part of the school day the medium of instruction is immersion language one, and during the second part immersion language two is used. Naturally, first language instruction is also included as a third element in this kind of program. In Europe, where two or three languages are often obligatorily included in regular compulsory schooling, an increasing portion of European immersion programs now orient themselves toward multilingual goals, where a main immersion language is extended with additional languages as well. For the additional languages the results are encouraging, as students appear to be able to benefit from having learned the main immersion language (see Björklund, 2005; Cenoz, 2009).

Conclusion

Since its first implementation in the mid-1960s, immersion education has grown rapidly in both variety and diversity. There are a few crucial distinguishing features which have remained constant across this diversity of contexts, populations, and motives for establishment. The intensive second language exposure within the program has led to closer investigation of immersion programs than many other language-related programs. Because of this scientific interest in immersion, much is known about how immersion works, and the design of future programs can be backed up with an abundance of research results. On the other hand, more research is needed in order to explore pending issues, particularly sociolinguistic factors such as the status of individual languages in different contexts and their relationship with the motivational and attitudinal dimensions that in turn influence students' language learning processes and outcomes.

Immigrant Discourse

ANNA DE FINA AND MIKE BAYNHAM

Introduction

Before introducing the topic of this entry, it needs to be clarified that the term *discourse* is employed here to refer to language in use as organized and culturally shaped ways of talking embedded in concrete social practices (see Gee, 1996, p. 131, on this point). Discourse refers here both to ways of representing reality and ways of linguistically interacting. Bearing this definition in mind, it can be said that the study of discourse phenomena related to migration is relatively recent. In the 1980s and 1990s migrants and migration figured in linguistic research mostly in indirect ways in that migrants were seen basically as agents or patients of important linguistic processes that were of interest to different disciplines within the field. For example, within language acquisition research immigrants were constructed as “L2 learners” and their linguistic productions were analyzed in order to demonstrate the existence of interlanguages, that is, intermediate linguistic systems that develop dynamically toward the target language (see Krashen, 1982), or of natural sequences of acquisition of grammatical constructions in different languages (see Rutherford, 1982).

Immigrants and immigrant languages also figured prominently in sociolinguistics, particularly in studies of language contact (a field inaugurated by Haugen, 1953) and of phenomena related to it. Within sociolinguistics immigrants were regarded as speakers of “minority languages,” or “languages of origin,” and as bilinguals, multilinguals, or both. Scholars were trying to assess how the languages they spoke changed over time through contact with other languages, to what extent they underwent partial or complete shift, what social factors influenced those changes. To this extent research into “stable” language varieties has always been informed by an understanding that these were shaped by processes of migration and mobility, but in classic sociolinguistics language forms migrated rather than people: thus, the focus remained still very much on language structures.

An exception to this trend was the subfield of code-switching studies (Blom & Gumperz, 1972/1986) in which analysts were developing more dynamic models to explain how and why bilinguals shifted from one language to another, mixed different language varieties, or both. Scholars within that field who took an interactional perspective started becoming interested in the discourse dynamics of those switches and their function in terms of identity negotiations (Auer, 1998). The sociolinguist John Gumperz (1982) also underscored the significance of different cultural/pragmatic expectations and modes of communication in intercultural encounters. Thus, “immigrants” and their ways of using language started occupying center stage in studies of intercultural communication, as is still evident in the research into immigrants and institutional encounters (whether related to health, education or work) which is described below.

These different traditions in linguistics have something in common: they were not focusing on immigrants as such or on migration as a social phenomenon, and were mostly concerned with the language varieties spoken by immigrants rather than with discourse by and about immigrants. In the late 20th and early 21st century the situation changed radically with the development of a more socially responsive sociolinguistics and the shift

of attention to discourse. Over this period as well interest in migration spread exponentially in all the social sciences. Indeed, migration has become an extraordinarily visible phenomenon due, among other things, to the increased internal and external mobility that characterizes postmodern societies, globalization phenomena that allow for unprecedented connections between people who are spatially and geographically separated, the increase of multilingual and multicultural contact spaces in the world, and the centrality of discourses about migration in political struggles all over the planet. All these phenomena have brought migration and immigrants to the attention of discourse analysts, contributing to the birth of a new burgeoning field of inquiry.

In this entry the focus is on discourse-based approaches to migration, that is, on studies that have the following broad foci: *discourse on immigrants*, *discourse by immigrants*, and *institutional interactions involving immigrants*. We conclude by briefly reviewing a developing research agenda studying the multilingual performance of the children (and grandchildren) of immigrant families, which might be called a *discourse of polylingual performativity*, and considering the impact of new digital media in shaping the language practices of the 21st century, including of course discourses of migration.

Underpinning the development of these areas of studies has been a theoretical shift in focus in sociolinguistics and discourse studies. One aspect characterizing this shift has been the move toward the investigation of new configurations of time and space brought about by processes of globalization and therefore the birth of a sociolinguistics of movements and flows which does not presuppose the existence of stable relations between identities, languages, and places or a neat separation between centers and peripheries. A second important aspect has been the focus toward the study of interactional sites and processes that clearly reveal the impact of power struggles and of the unequal distribution of linguistic resources on the life of individuals and communities.

Discourse on Immigrants and Migration

One strand of research engages with the discursive representations of immigrants and migration in the public domain. Analyses focus on policy, the legislative sphere, and the political rhetoric that drives it, but also on the media (indeed in questions of immigration, the discourses of the media and public policy can be seen as very closely calibrated). Methodologies for such studies include critical discourse analysis, corpus analysis, and linguistic ethnography. However, most research, particularly on parliamentary discourse and on representations of immigrants in the press, is inspired by critical discourse analysis (e.g., Martín Rojo & van Dijk, 1997, on Spanish parliamentary debates), sometimes combined with other methodologies such as corpus analysis (e.g., Baker et al., 2008). Critical discourse analysis focuses on ways in which power abuse and inequality are enacted and reproduced in and through discourse, thus researchers in this field regard public discourse on migration as embedded in wide social processes linking it to ideological constructs and practices such as nationalism (Wodak, de Cillia, Reisigl, & Liebhart, 1999) and racism (van Dijk, 1993). It has been shown in the literature that the post-9/11 discourses identified as dominant are increasingly driven by nationalist agendas and anxieties over borders, community cohesion, and security. At the same time, researchers have noted how there has been an analogous increase in emphasis in the public policy domain on citizenship, integration, and social cohesion as closely linked to competence in the national language. Thus, recent studies illustrate how mainstream language ideologies have informed the policies regulating and implementing language testing in connection with the acquisition of citizenship (see Piller, 2001). This research of course targets what Hinnenkamp (2003) has called “they codes” rather than “we codes,” and public discourses which contribute to “othering” immigrant subjects by speaking of, or about, or for “them,” rather than

opening up spaces where “they” may have a voice or acquire discursive agency. A discussion on the question of voice and the speech/writing of the immigrant subject now follows.

Discourse by Immigrants

Psychologists regard migration as one of the processes that most profoundly unsettle and reshape people’s life. The focus of their studies is on the cognitive and emotional states of the individual. But there is also a great deal of research on migration in the social sciences that has traditionally focused on social processes and structures. The phenomena that have received the most attention are assimilation processes as measured and assessed through the use of quantitative measures and external indexes such as intermarriage rates or language maintenance. However, discourse perspectives on migration start from very different theoretical and methodological premises. On the one hand, they emphasize the need to analyze what migrants themselves say about their experience in order to understand the processes that change their lives. On the other hand, they argue for the constitutive nature of discourse in the construction of identities, stances, and worldviews. It should not come as a surprise then that many of the studies that take as their object the discourse of immigrants, that is, the way they construct and represent their experiences, have focused on narratives.

The “narrative turn” in the social sciences (Bruner, 1991) has indeed had a strong impact on the kind of research that has been conducted in the field in the last 30 years. Narrative turn proponents emphasized the importance of qualitative research as a way of understanding social phenomena and proposed narrative both as a data collection tool and as an object of analysis. For narrative turn analysts giving people the opportunity to tell their stories was also a way of providing them with the possibility of being heard. From a similar perspective then, narratives of migration are seen as particularly useful to study and understand how people deal with social processes of uprooting and “unsettlement,” or more in general, with great personal and social changes (Baynham & De Fina, 2005). Thus, scholars in this field are interested in the ways in which people reconstruct traditional processes of displacement from one country to the other, but also how they talk about country internal displacements due to forced relocation or border changes.

The Discursive Construction of Immigrant Identities

Interest in narratives told by immigrants also centrally concerns the construction of identities as scholars investigate how immigrants deal with the “unsettling” of stable notions of self and of place and how they express and negotiate belonging. Work on identity and narrative investigates different aspects that may both reflect existing self-perceptions by immigrants and shape them. As immigrants leave their countries they are forced to abandon old definitions of who they are and to find new ones. At the same time, they are confronted with inventories of identities that are imposed on them through public discourses and practices. Thus, some scholars have focused on ways in which immigrants categorize themselves in terms of ethnicity, gender, and class on their positioning with respect to existing social identity categories (see De Fina, 2003, 2006; Pavlenko & Blackledge, 2004; Meinhof & Galasinski, 2005). Research on life stories told by immigrants has also brought to light questions of agency and coherence showing how difficult it is for people who have been uprooted to achieve a sense of purpose and empowerment (McElhinny et al., 2008).

Narrative analysts have also greatly contributed to sociolinguistic reflection on the relationships between identity, space, and place as they have pointed to the many discourse

strategies and mechanisms through which narrators index affiliations and emotional belonging through positioning in space and time, for example, by tying distance or closeness to different places and moments (see Baynham, 2004).

The study of the construction and negotiation of identities by immigrants is not confined to narratives told in interviews but extends to many other kinds of communicative situations and to different generations (for example children or descendants of immigrants). For example, recent studies have analyzed identity displays in family interactions (Giampapa, 2004) and peer group conversation or play (Lytra, 2007). Finally, as will be seen below, scholars have focused on language styles and performance, particularly among young immigrants and the children of immigrants, as indexes of distinct identities (Jørgensen, 2008).

Another area in which research on immigrant identities has been particularly productive is the investigation of discourse by immigrants in relation to L2 usage and learning. Psychological and social processes related to speaking a minority language or learning the language of the host country are objects of reflection and occasions for different kinds of positioning for immigrants. Thus research in this area investigates, for example, how learners conceptualize their own success or failure and their belonging to or distancing from the national community (see Farrell, 2008), what kind of “investment” (Norton, 1995) or emotional involvement connects them to their second language, and how they talk about their language experiences (De Fina & King, 2011).

In all these studies identities are seen as constructed and negotiated in discourse and interaction, and therefore as essentially multiple and hybrid. Thus, research on immigrant identities has contributed to dispelling preconceived and stereotyped notions about immigrant communities and individuals. At the same time, researchers in the field have also promoted a reflection on the centrality of power processes in the construction of identities, particularly in the case of vulnerable social subjects such as immigrants.

Institutional Interaction Involving Immigrants

A further strand of research examines the interactions of immigrants in institutional contexts. This research is based on two simple, interrelated, but far-reaching propositions: (a) that for migrants in a new society, access to the crucial material and symbolic resources that enable survival and integration is mediated through repeated face-to-face interactions with institutions; (b) that these face-to-face interactions are significantly shaped by changing policy environments and institutional arrangements as well as sometimes volatile national political and media attitudes toward diversity, integration, citizenship, and accompanying ideologies concerning who should have access to what resources, and how.

Drawing on well-established frameworks for investigating institutional discourse, this research aims to analyze the role of language practices in the domains of *health*, *education*, and *work*, to understand how language practices in these domains are shaped both by the dynamics of face-to-face encounters and by the constraints of the political, policy, and institutional environment. Among the questions posed are the following: What linguistic factors enable and constrain access for migrants to health services, education, and work, what languages and forms of communication get used, when, why, and where, and what are the consequences for the migrant? Institutions can organize and deploy communicative resources by using different modes (oral and written) and modalities (visual, with mediators or interpreters, formal and informal, via written language). Not all such communicative practices are the same and the way they get organized (or not) in a given institution has consequences for migrants seeking access to services and resources.

Applied linguistic research in the area of health relevant to migration has focused overwhelmingly on issues of intercultural communication and mediation through formal and

informal interpreting and cultural brokering (see Valdes & Angelelli, 2003). Unsurprisingly, the most characteristic research focus has been on the medical consultation. Microanalysis of interpreted interactions shows the voice of the patient often disappearing as a result of selective interpreting, and the interpreter's alignment with and recruitment into the communicative purposes of the physician (see Davidson, 2000). The interpreted medical consultation is an example of what is known as a gatekeeping encounter, another area in which research has been productive. Indeed, in relation to the workplace, the research of Roberts and Campbell (2005) examines employment interviews as gatekeeping devices for migrant applicants whose education and work experience has been largely out of the UK, identifying a "linguistic penalty" for migrant applicants, if their education, training, and work experience has been in their country of origin.

Historically education has been the most sustained area of focus for applied linguistic work on the language situation of immigrants. Research has focused on (a) education and training provision for adult migrants, either on arrival or ongoing (see Cooke & Simpson, 2008), and (b) the language issues involved in the education of the children of migrants, both in mainstream schooling and in complementary schooling (see Blackledge & Creese, 2009). Issues in relation to (a) include language learning opportunities and access to them through policy (see Cooke & Simpson, 2008; Baynham & Simpson, 2010), particularly the current impact of citizenship on ESOL pedagogy (see Cooke, 2006), the learning trajectories of ESOL learners (see de Costa, 2010), and, indeed, the learning identities of bilingual learners (see Kanno & Norton, 2003; De Fina & King, 2011). Issues in relation to (b) include the impact of policy, linguistic barriers to access to curriculum achievement in the dominant language, and also opportunities to maintain and develop bilingual skills. In relation to the education of children from migrant communities, important studies look across from home to school and back again (see Gregory & Williams, 2000).

In Conclusion: Toward Norms of Polylingual Performativity

As suggested above, the official and public discourses on immigrants and immigration as exemplified in the media, in language policies, and the law are constructed within a frame of nations, borders, security, and integration, and of othering processes such as the construction of a "they" rather than a "we." This orientation is indeed embedded in the term immigration itself (in-migration, immigrants are the ones who come in, "they" cross "our" borders) and reflected in the highly emotional language used by the media to talk about this topic. Oral narrative creates a space for immigrant voices, one of the reasons why it is so significant in the articulation of identities. Institutional interactions provide other opportunities for agency, despite the formidable forces and constraints that work against the rights of marginalized people in such contexts, as shown in Maryns's (2006) work on the silencing of asylum seekers in official interview.

In conclusion, some current trends and directions in research that look beyond the borders of the nation-state to migration trajectories, transnational spaces, and flows are examined. As Low and Lawrence-Zuñiga have put it: "This process of cultural globalization creates new translocal spaces and forms of public culture embedded in the imaginings of people that dissolves notions of state-based territoriality" (2003, p. 25). This tendency combines with the emergence of new linguistic and cultural practices among second and third generation members of immigrant families as shown in research by Hinnenkamp (2003) and Jørgensen (2008) who analyze emergent polylingual styles among young people of immigrant origin. A further development which troubles the stability of the nation-state construct is the diffusion of new digital media which, as Lam (2006) and others have shown, are creating online and virtual spaces for transnational multilingualism. Warschauer (2009) points out how the translocal varieties produced in these contexts often involve

multilingual mixes and blends, such as switches to Arabic or Chinese incorporated into English orthography. No doubt it is out of these emergent social and linguistic forms that future discourses of migration in a globalized and networked world will be shaped.

Implicit Learning in Second Language Acquisition

PATRICK REBUSCHAT AND JOHN N. WILLIAMS

The process of implicit learning, essentially the ability to acquire unconscious knowledge, is an elementary and ubiquitous process of human cognition. Everyday life offers many examples of implicit learning: First language, socialization, music perception, and many other skills are often thought to be acquired in an implicit fashion (Berry & Dienes, 1993). The field of second language acquisition (SLA) has a long-standing interest in implicit and explicit learning (see DeKeyser, 2003; Williams, 2009, for overviews). To a large degree, this interest was sparked by Krashen's (1981) proposals and the ensuing debates on the implicit–explicit interface. In the following entry, we will first define the term *implicit learning* and briefly describe characteristics of implicit knowledge. We will then discuss (lack of) awareness as a criterion of implicitness and review several studies that focused on the implicit learning of a second language (L2). The entry concludes with suggestions for future research.

What Is Implicit Learning?

The term implicit learning was first employed by Arthur Reber (1967) to describe a process during which subjects acquire knowledge about a complex, rule-governed stimulus domain without intending to and without becoming aware of the knowledge they have acquired. These two dimensions, *intentionality* and *awareness*, are central to the notions of implicit and explicit learning in the psychological literature. In the research tradition started by Reber (1967), the use of the term *implicit* is generally restricted to those situations where subjects have acquired unconscious (implicit) knowledge under incidental learning conditions. If incidental exposure in an experiment results in conscious (explicit) knowledge, for example, when subjects were able to figure out the rule system despite not having been told about its existence, the learning process is usually only characterized as being incidental and not as implicit. The same applies for those experiments that do not include a measure of awareness. The term *explicit learning* is usually applied to learning scenarios in which subjects are instructed to actively look for patterns, that is, learning is intentional, a process which tends to result in conscious knowledge.

In Reber's (1967, exp. 2) seminal study, subjects were given letter strings such as TPTS, VXXVPS, and TPTXXVS and simply asked to memorize them. Unbeknownst to the subjects, the arrangement of letters was determined by a finite-state grammar. After the memorization task, subjects were informed that the previous letter sequences had been generated by a complex system. They were then given new letter sequences, only half of which followed the same grammar, and instructed to judge whether the test sequences were grammatical or not. Reber (1967) found that subjects judged 79% of all letter sequences correctly, which indicated that simple memorization of grammatical strings was sufficient for subjects to derive information about the underlying grammar. Interestingly, when asked to verbalize the rules that generated the letter strings, subjects were unable to do so. In other words,

subjects were able to acquire knowledge without intending to (after all, they did not know they were going to be tested, nor were they informed in advance about the existence of the grammar) and without becoming aware of the acquired knowledge (they were unable to verbally describe the grammar). Reber (1967) used the term implicit learning to differentiate this process from that of explicit learning, a learning process where the individual deliberately forms and tests hypotheses about the stimulus domain.

The past decades have resulted in a relative consensus on several characteristics of implicit learning and knowledge. For example, Reber's (1967) basic finding that subjects can exploit the structure inherent to the stimulus environment incidentally has been frequently replicated and appears very robust. It is widely accepted that implicit learning gives rise to a sense of intuition, that is, "people do not feel that they actively work out the answer" but rather make "particular responses because they 'feel' right" (Berry & Dienes, 1993, p. 14). Implicit knowledge seems to be more robust in the face of neurological disorder (e.g., Knowlton, Ramus, & Squire, 1992) and in the face of time, that is, it appears longer lasting than explicit knowledge (Allen & Reber, 1980). In contrast to explicit learning, successful implicit learning is less affected by individual differences (Reber, Walkenfeld, & Hernstadt, 1991), and it also seems to place fewer demands on attentional resources (e.g., Dienes & Scott, 2005).

Awareness as a Criterion of Implicitness

Despite the considerable interest in the topic of implicit and explicit learning within the field of SLA, we know surprisingly little about the contribution of implicit learning to L2 acquisition. This is, in part, due to methodological reasons. Although there are several theories about the role of implicit and explicit L2 learning, it is difficult to adjudicate between them because of the difficulty of determining whether exposure resulted primarily in implicit or in explicit knowledge (Williams, 2009). If we intend to characterize the contribution of implicit learning to L2 acquisition, we need to be able to measure whether the acquired knowledge is implicit or explicit.

In psychology, the most commonly used criterion for disentangling these types of knowledge is awareness (or lack thereof). Implicit knowledge is unconscious knowledge which subjects are generally not aware of possessing. Explicit knowledge is conscious knowledge which subjects will be aware of possessing, though they might still not be able to verbalize it. There are several ways of measuring whether or not the acquired knowledge is conscious or unconscious (see Rebuschat, *in press*, for a comprehensive overview).

One of the most common procedures is to simply prompt subjects, at the end of the experiment, to verbalize any rules they might have noticed while performing on the exposure task. In this case, knowledge is considered to be unconscious when subjects show a learning effect (e.g., above-chance performance on a grammaticality judgment task), despite being unable to describe the knowledge that underlies their performance (e.g., Reber, 1967).

Another possibility is to compare subjects' performance on direct and indirect tests. The *direct* test is a measure that explicitly instructs subjects to make use of their knowledge (e.g., an untimed grammaticality judgment task). The *indirect* test assesses subjects' performance without instructing them to use their acquired knowledge (e.g., an elicited imitation task). Ideally, subjects should not even know they are being tested. Here, knowledge is considered unconscious if an *indirect* measure clearly indicates a learning effect (in our example, spontaneous self-correction of ungrammatical items during the elicited imitation task), even though a *direct* measure shows no evidence of learning (e.g., subjects are unable to distinguish grammatical and ungrammatical items when asked to do so).

Finally, one could also determine whether subjects acquired conscious or unconscious knowledge by collecting confidence ratings and judgments about the kind of knowledge

used to make the decision, known as “source attributions” (Dienes & Scott, 2005). This can be done, for example, by asking subjects to perform on a grammaticality judgment task and to indicate, for each judgment, how confident they were in each decision (e.g., guess, somewhat confident, very confident) and what their decision was based on (e.g., guess, intuition, memory, rule knowledge). Subjects’ knowledge can be considered unconscious when (a) the grammaticality judgments for which subjects reported to be guessing are actually significantly above chance, and (b) when there is no correlation between the reported confidence level and the observed level of accuracy. In both of these cases, subjects are not aware of having acquired knowledge.

What Can Be Learned Implicitly in L2 Acquisition?

Very few studies explore systematically the acquisition of implicit knowledge by L2 learners. In SLA, a significant body of work has investigated incidental language learning (see Hulstijn, 2003, for a review), but these studies tend to concentrate on vocabulary acquisition and do not include measures of awareness, so it is unclear whether the acquired knowledge is actually implicit. Numerous SLA studies have compared implicit and explicit instructional methods, and even though explicit instructional methods produce larger learning effects than implicit methods it is still not clear to what extent either instructional approach resulted in truly implicit knowledge. There is also a large body of work in developmental psychology, especially in the statistical learning tradition (see Saffran, 2003, for a review), but here the learning conditions are sometimes far from incidental (e.g., subjects might be instructed to actively discover words in a continuous speech stream), nor do these studies include any measures of awareness. The review below will focus on studies that exposed subjects to the target structures under incidental learning conditions and established that the acquired knowledge was implicit according to the awareness criterion.

Form–Meaning Connections

The ability to associate forms and meanings lies at the heart of language learning and processing, and there is evidence that adult learners are able to acquire novel form–meaning mappings implicitly (e.g., Williams, 2005; Leung & Williams, 2011). For example, Williams (2005) exposed subjects to a semi-artificial language consisting of English words and four artificial determiners (*gi*, *ro*, *ul*, and *ne*) which encoded both distance (near vs. far) and animacy (animate vs. inanimate). At the beginning, subjects were told that the determiners functioned like English determiners, except that they also encoded distance: *gi* and *ro* were used for near objects, while *ul* and *ne* were used for far objects. Importantly, subjects were not informed that the artificial determiners also encoded animacy: *gi* and *ul* were used with animate objects, whereas *ro* and *ne* were used with inanimate objects. The role of animacy in determiner usage thus served as a hidden regularity. Subjects were exposed to the semi-artificial language under incidental learning conditions, that is, they did not know they were going to be tested. Retrospective verbal reports served as a measure of implicit and explicit knowledge. In the testing phase, Williams (2005) observed a significant learning effect: In a sentence completion task, subjects were significantly more likely to select determiners according to the noninstructed meaning dimension (here, animacy) even when they were completely unaware of its relevance to determiner usage.

Further support for Williams’ (2005) finding that subjects can acquire form–meaning connections implicitly comes from a study conducted by Leung and Williams (2011). Subjects were exposed to an artificial determiner system by means of a novel reaction time task. The study used the same system as Williams (2005), except that here *gi*, *ro*, *ul*, and *ne* encoded age (children vs. adults) and agency (agent vs. patient) instead of distance and

animacy. Before the experiment, subjects were told that *gi* and *ro* were used with personal names referring to adults, whereas *ul* and *ne* were used with personal names referring to children. Subjects were not told that the choice of determiner also depended on the thematic role of the noun phrase: *gi* and *ul* were used with agents, while *ro* and *ne* were used with patients. In the experiments, subjects saw a picture on the computer screen that was accompanied by an auditory description. For example, the trial might consist of a picture of a girl kissing a boy on the cheek and an auditory description such as “Kiss ul Mary a boy on the face.” The subjects’ task was to indicate the location of the named individual in the image (left or right) by pressing the appropriate response key. In the first 114 trials of the experiment, the artificial determiner system followed the rules outlined above, but in the final 16 trials (the violation block) the rules were reversed, that is, *gi* and *ul* were used with patients instead of agents. Learning was assessed by measuring the time it took subjects to identify the location of the named individual. The conscious or unconscious status of the acquired knowledge was assessed by means of verbal reports after each part of the testing phase.

The verbal reports showed that, at the end of the experiment, 80% of subjects remained unaware of the simple rules that determined the choice of determiners. Despite remaining unaware of the system these subjects’ response times to locate the named individual slowed significantly when the rule system was changed, suggesting that they had learned the relationship between the determiners and the thematic roles implicitly.

Syntax

In the case of syntax, several studies have shown that adult learners can acquire L2 syntax incidentally, that is, without intending to (e.g., Rebuschat & Williams, 2006; Cleary & Langley, 2007; Rebuschat, 2008). For example, Cleary and Langley (2007) focused on the retention of syntactic patterns as a result of incidental exposure. Adult subjects were presented with meaningless word sequences that followed the same syntactic pattern (essentially English phrase-structure, for example, *beautiful transportation shed temporary plants, mechanical consumers submit colder songs, efficient dreams write better umbrellas*, etc.) After exposure, subjects were given a recognition task that required them to rate the likelihood that each test item had been presented before. The testing set included three types of sequences: *studied strings* (repetitions from training), *critical lures* (novel sequences that followed the same pattern as the studied strings), and *new strings* (new sequences that did not follow the pattern of the studied strings). Cleary and Langley found, as expected, that subjects rated studied strings highest and new strings lowest. Interestingly, however, they also found that ratings were significantly higher for critical lures than for new strings. In other words, if a novel word sequence followed the same syntactic pattern as the training sequences, subjects were more likely to think that they had encountered it before, even if this was not actually the case. Cleary and Langley (2007) suggest that this ratings effect occurred because subjects derived an abstract representation of the syntactic structure underlying the training sentences. That is, incidental exposure to new word patterns resulted in knowledge that was, at least partially, independent of the items utilized in training.

Evidence that the acquisition of non-native syntax can occur not just without intention but also result in unconscious knowledge was provided by Rebuschat (2008) and Francis, Schmidt, Carr, and Clegg (2009). Rebuschat (2008, exp. 3) exposed subjects to a semi-artificial language consisting of English words and German word order under incidental learning conditions. The exposure task required subjects to judge the semantic plausibility of 120 sentences, for example, “In the evening explained Rose that the profit below the estimate remained” (plausible) and “Today beheld Chris that the earth around the tomato

rotated" (implausible). The exposure task thus required subjects to process the sentences for meaning. In the testing phase, subjects were informed that the word order in the previous sentences was not arbitrary but that it followed a "complex system" instead. They were then instructed to listen to 60 completely new sequences, only half of which followed the same rule system as the one they had just been exposed to. Those sequences that did obey the rules should be endorsed as *grammatical* and those that did not rejected as *ungrammatical*. Importantly, subjects were not only required to judge the grammaticality of each item. They were also asked to report how confident they were in each grammaticality judgment (guess, somewhat confident, very confident) and to indicate what the basis of their judgment was (guess, intuition, memory, rule). The analysis of the grammaticality judgments showed a clear learning effect, that is, subjects were able to acquire the new grammatical system incidentally and to use this knowledge in a transfer task. The analysis of the confidence ratings and source attributions further showed that, while subjects were aware of having acquired some knowledge, this knowledge remained unconscious. In other words, subjects displayed intuitive knowledge of the L2.

Francis et al. (2009) investigated the incidental learning of basic word order patterns by adult native speakers of English. Subjects initially performed an oral reading task, during which they were exposed predominantly to one type of three-word sequences, depending on which group they had been assigned to. One group was exposed mostly to noun-noun-verb strings (say, *steak cop learned*), while the other group was exposed mainly to verb-noun-noun strings (*pierced Jane oil*). Both of these sequence types are *nondominant* in that they do not occur in English. The arrangement of the words was random, that is, no meaningful utterances were used. Subjects were presented with three-word strings and instructed to read the three words out loud. Oral reading time for each sequence was used as an indirect measure of learning. The first phase of the reading task (eight learning blocks) served to expose subjects to exemplars of the nondominant word order. The second phase (one testing block) was used to assess whether subject groups had acquired knowledge about their respective training sequences and whether this knowledge could be generalized to novel sequences with the same underlying structure. Francis et al. found that reading speed decreased as a result of exposure and that this pattern held for strings encountered during the learning blocks as well as for strings that followed the nondominant word order but had not been presented before. Their study confirms that adults can acquire new word order patterns incidentally and that the exposure resulted in abstract, generalizable representations. Interestingly, Francis et al. also report that only a few subjects were able to generate strings that followed the training pattern when prompted to do so in a grammar generation task. This suggests that the incidental exposure resulted, at least in some participants, in implicit knowledge.

Future Directions

A review of the literature on implicit language learning shows that adult learners are able to acquire form–meaning mappings and L2 syntax without becoming aware of the acquired knowledge. At the same time, we know relatively little about several key aspects of implicit L2 learning. First, we need to know more about what aspects of the L2 can and cannot be acquired as a mere result of exposure and without explicit treatments. Second, the issue of individual differences in implicit and explicit L2 learning has received very little attention, despite its relevance for classroom instruction. Third, we need to know more about the influence of prior knowledge. For example, how does prior linguistic knowledge (L1, L2, L3 . . .) influence the implicit learning of a new language (L2, L3, L4 . . .)? Finally, we know too little about the role of attention in implicit L2 learning. There is a vast literature

that focuses on the role of attention in L2 learning, but the aim of these studies is to examine whether or not awareness correlates with learning and not to investigate what demands, if any, implicit learning places on attentional resources. Considerably more empirical research is necessary before the precise role of implicit learning in L2 acquisition can be fully determined.

Incidental Learning in Second Language Acquisition

JAN H. HULSTIJN

The term incidental learning is used, in applied linguistics, to refer to the acquisition of a word or expression without the conscious intention to commit the element to memory, such as “picking up” an unknown word from listening to someone or from reading a text.

Imagine someone asked you to describe the living room of a house you have often visited, such as the house of your best friend. You will probably have no difficulty in describing the room and the items in it, in great detail, although it is unlikely that you ever made a deliberate attempt to remember as much of this room as you can. You will probably have no difficulty either remembering the room of the hotel you were staying in, for a single night, a couple of weeks ago. But it is unlikely you will remember the room of the hotel where you spent a night three years ago. These examples illustrate, in an informal way, what is usually meant when researchers say that people “incidentally learn” or “pick up” factual knowledge, such as words, names, dates, events, descriptions, or explanations seemingly without effort.

Incidental learning stands in contrast to intentional learning, which refers to a deliberate attempt to commit factual information to memory, often including the use of rehearsal techniques, like preparing for a test in school or learning a song by heart.

History of the Terms Incidental and Intentional Learning

The terms incidental and intentional learning were originally used in the middle of the 20th century in the heyday of American behaviorist psychology, conceptualizing learning in terms of stimulus-response contingencies (Postman & Keppel, 1969). Researchers experimentally investigated human learning by providing human subjects with information (such as a list of words) under two conditions. In the intentional condition, subjects were told in advance that they would afterwards be tested on their recollection of the materials to which they were going to be exposed. Subjects in the incidental condition were not told that they would be later tested. Thus, originally, the terms incidental and intentional learning referred to a methodological feature of learning experiments, pertaining to the absence or presence of a notification whether subjects would be tested after exposure. Later, psychologists used incidental-learning experiments in combination with different orienting tasks. For instance, Hyde and Jenkins (1973) asked subjects to rate each word in a word list as to their pleasantness (a semantic orienting task) or to record the part of speech of the words (a nonsemantic orienting task). When subjects were later given a surprise recall task (i.e., in an incidental-learning setting), subjects in the semantic condition were able to recall more words than those in the nonsemantic condition.

Bransford, Franks, Morris, and Stein (1979) introduced the notion of *transfer-appropriateness* to explain why they found, in a learning experiment involving word lists, that participants who had been administered compatible learning and recall tasks (semantic-semantic, or nonsemantic-nonsemantic) achieved higher retention scores than participants who were given incompatible learning and recall tasks (semantic-nonsemantic, or nonsemantic-semantic).

DOI: 10.1002/9781405198431.wbeal0530

The notion of transfer appropriateness may help to illustrate the difference between incidental and intentional learning. Thus, as participants in an intentional vocabulary learning task are told in advance that they will be tested after the learning phase, they will try to store the to-be-learned word information in a form perceived as transferable to the test situation. In contrast, processing instructions during the learning phase in an incidental learning setting may or may not be conducive to successful transfer to the test situation. For instance, participants in an incidental learning vocabulary learning experiment who are instructed to pay attention to the meaning of some new words which appear in a reading text are likely to perform much better on an unexpected receptive posttest than on an unexpected productive posttest.

The notion of transfer-appropriateness also underscores the crucial importance of the instruction (in learning experiments often called the orienting task) because the instruction is the instrument with which the researcher or teacher can control or manipulate students' attention to the information to be learned.

In 1972, Craik and Lockhart proposed the depth-of-processing theory, claiming that the chance that some piece of information will be stored in long-term memory is not determined by the length of time that it is held in short-term memory but rather by the shallowness or depth with which it is initially processed. This theory has survived, in adapted form, until the present day (Lockhart & Craik, 1990; Craik, 2002). Laufer and Hulstijn (2001) used Craik and Lockhart's depth-of-processing theory to formulate their involvement hypothesis for second language vocabulary learning. Laufer and Hulstijn (2001) proposed the notion of *involvement*, consisting of (a) a motivational component, comprising the *need* to determine a new word's meaning, and (b) a cognitive component, comprising *search* (e.g., dictionary look up) and *evaluation* (e.g., evaluating whether the information obtained from the dictionary applies to the verbal and nonverbal context). Retention of hitherto unfamiliar words is claimed to be conditional, in general, upon the degree of involvement in processing these words. (For a detailed account of the history of the terms incidental and intentional learning, see Hulstijn, 2001, 2003.)

Incidental and Intentional Learning Versus Implicit and Explicit Learning

In the applied linguistics literature, the terms incidental and intentional learning are sometimes used in connection with the terms implicit and explicit learning. Although the meanings of incidental and implicit learning and the meanings of intentional and explicit learning overlap, they refer to different constructs in different domains of inquiry. The terms implicit and explicit learning are used in current theories of second language acquisition (and in cognitive science in general) to refer to, respectively, the unconscious and conscious learning of facts or regularities in the input materials to which subjects in learning experiments are exposed. In second language acquisition studies, the regularities usually pertain to grammatical phenomena (e.g., a morphosyntactic rule). Implicit knowledge is believed to be spread out over various regions of the neocortex, while explicit knowledge is assumed to reside in a particular area of the brain (the medial temporal lobe, including the hippocampus), independent of the areas where implicit knowledge resides. In this (neuro)cognitive domain of scientific inquiry, implicit and explicit learning are sometimes said to take place incidentally and intentionally, but these two labels do not play a crucial role in theoretical accounts of learning, simply because the behaviorist learning theories of the previous century have lost their prominent role. In contrast, the terms incidental and intentional learning are still being used in the vocabulary-learning literature, albeit not associated to current cognitive or neurocognitive theories of the processing mechanisms

involved in learning or the locus of learned information (Hulstijn, 2005).

Word Knowledge

Before considering several factors affecting vocabulary learning, whether incidental or intentional, it is important to properly understand what it means to know a word.

A lexical entry in the mental lexicon of the average adult, literate, native speaker contains a number of semantic features (its core meaning or meanings, its pragmatic and stylistic meanings, and the collocations in which it frequently occurs) and a number of formal features (its grammatical word class, its morphophonological make up, its auditory and articulatory phonetic forms, and its orthographic shape). The features of a lexical entry are intrinsically or associatively related to each other and to features of other entries, even across language boundaries (involving translation equivalents in another language) while the strength of these relationships may vary (Meara, 2009). Generally, the most difficult association for a first or second language learner to acquire, is the association between the word's core meaning and its phonological form because, for a large majority of so called base words (monomorphemic words), the association is completely arbitrary (e.g., why is a dog called "dog" and not "cat" or "table" or "sanon"?).

The Acquisition of a Large Vocabulary

Although estimation figures differ, it is safe to say that adolescent native speakers of English who have completed high school, have a receptive vocabulary of at least 20,000 base words (i.e., words without the inflectional forms, derivations or compounds that can be made of it, such as "open," but not "opened," "opener" or "door opening") (Nation, 2001). The accepted view is that they cannot have learned such a large number of words solely by means of explicit vocabulary instruction. Rather, they must have learned most words in an incremental way through repeated encounters through listening and reading. Furthermore, even though many words (in L1 and L2) are learned intentionally in the context of the school curriculum, not all words learned intentionally will be remembered for ever. In general then, several interrelated questions need to be answered. First, if it is true that most of the information stored in people's memories has been "picked up" incidentally, how do we explain this phenomenon of incidental learning? Why do people not pick up *all* information to which they have been exposed? Second, why do people not retain all information that they have learned intentionally? In a nutshell, the answers to these questions read as follows. Learning, whether incidental or intentional, is mainly a matter of selective attention and elaborated processing, or, as Eysenck (1982, p. 203) put it: "memory performance is determined far more by the nature of the processing activities engaged in by the learner than it is by the intention to learn per se." In other words, a critical feature of human memory appears to be *how* one processes information and not whether one processes information with or without the intention of remembering (Baddeley, 1997; Craik, 2002). Rich, elaborate processing, however, is not enough either. New information will seldom leave a lasting trace in memory if not frequently reactivated, what Baddeley (1997, p. 123) called "elaborative rehearsal," involving the formation of connections between the new information and information already known. In the case of learning a new word, processing of it in different contexts will create and strengthen its links with other words in the mental lexicon, increasing its recall. What we commonly call "forgetting" is mainly a matter of not using information frequently, whether picked up incidentally or learned intentionally. This fact is succinctly expressed by the common phrase "use it or lose it." In conclusion, asking the question of whether people with large vocabularies have acquired

the words in it incidentally or intentionally is not instrumental to explaining people's success in the acquisition of large vocabularies. While the absence or presence of a learning intention does not play a decisive role, vocabulary acquisition is first and foremost determined by the nature and frequency of the processing of new words.

Consequently, the recommendation of massive reading and listening activities and the discouragement of intentional vocabulary learning is based on an ill-informed understanding of the terms incidental and intentional learning. Incidental vocabulary learning is not necessarily more effective than intentional learning nor is intentional vocabulary learning more effective than incidental learning. Incidental acquisition-through-reading is a slow and error-prone process with small vocabulary gains (Nation, 2001; Read, 2004; Laufer, 2005; Brown, Waring, & Donkaewbua, 2008). Readers do not always notice unfamiliar words when reading a text. If they do, guessing the meaning is not always possible. Moreover, many people possess poor inferencing skills. Thus an incidental task (i.e., a task without forewarning that a retention test will follow) allowing learners to process new vocabulary only superficially or even skip new words altogether will produce little knowledge of new words. In contrast, one could think of an intentional task (i.e., a task with forewarning of an upcoming retention task) forcing learners to process new vocabulary elaborately (e.g., "read the following text, look up the meaning of any words you don't know in your dictionary, summarize the text's contents in about five sentences, and learn the new words looked up. You will later be tested on your knowledge of the words in this text"). The last ten years have witnessed the publication of dozens of studies (e.g., Peters, Hulstijn, Sercu, & Lutjeharms, 2009), giving empirical evidence for the claim that the low incidence of vocabulary acquisition through reading ("input only") can be substantially boosted by techniques that make students *look up the meaning* of unknown words, *process* their form-meaning relationship *elaborately*, and process them *again* after reading ("input plus").

Incidental Vocabulary Acquisition

SUSANNE ROTT

Incidental vocabulary acquisition is generally described as the “picking up” of new words when students are engaged in a reading, listening, speaking, or writing task. That is, incidental acquisition refers to the absence of the conscious intention to commit a word to memory. It is not to be confused with the notion of implicit learning. For example, we talk about incidental acquisition when a learner encounters an unfamiliar word in a text, attempts to understand its meaning to better comprehend the text, and is able to recall the word (or parts of it) after having completed the reading task. Typically readers attempt to understand the word by making an educated guess about the meaning from context (inferencing), glancing at a gloss (L1 translations or L2 synonyms) in the margin of the text, or by looking up the word in a dictionary.

Incidental Vocabulary Acquisition Through Reading

Since the 1990s incidental vocabulary acquisition has become a central research area for adult second language lexical development. Acknowledging the number of about 15,000–20,000 word families (Nation & Waring, 1997) a second language learner has to acquire to reach advanced language levels, Krashen (1989) argued in his seminal article that the majority of words cannot be learned by looking them up in a dictionary. In the context of his input hypothesis, he proposed that vocabulary and spelling is mostly acquired through exposure to comprehensible input such as reading. Further recognizing the complexity of the mental lexicon, researchers agree that students cannot develop a functional second language lexicon only by memorizing the bilingual word lists found in most textbooks. In fact, besides a word’s basic meaning, orthography, pronunciation, and word class, advanced language use requires the command of a word’s pragmalinguistic functions, its syntactic frames, and its meaning in conventionalized and metaphorical expressions (e.g., Nation, 2001; Schmitt & Carter, 2004). Naturally, reading provides rich lexical input which is vital to developing many of these aspects of words. Ellis described reading as the “ideal medium” for vocabulary acquisition. Print material allows learners more time for processing a new word, “whereas in speech [the word] passes ephemerally” (1994, p. 40). Yet, studies assessing the default hypothesis of reading as a main source for lexical development have shown that only a small number of words are “picked up” during reading (e.g., Horst, Cobb, & Meara, 1998).

Consequently, reading as a main source for lexical development may be too unpredictable in an instructed language-learning setting where advances in word learning need to be assessed. In fact, studies on word inferencing and text comprehension have shown that learners need to know about 95–8% of the words in a text to comprehend the text well enough to be able to infer the meaning of unfamiliar words (Laufer, 1992; Hu & Nation, 2000). Coady (1997) described the relationship between literacy skills and lexical learning as being both a vicious and a virtuous circle. L2 readers who have not developed fluency in reading read slowly, stumble over words, and have limited text comprehension. As a result they dislike reading, read infrequently, and thereby have infrequent opportunities for incidental word acquisition. In turn, L2 readers with a larger L2 lexicon and strategic

2 INCIDENTAL VOCABULARY ACQUISITION

higher-order reading skills comprehend text better, read more frequently, and therefore have more opportunities for lexical growth.

Cognitive Processes

Other studies have drawn attention to the cognitive mechanisms involved in acquiring words while reading. For instance, Hulstijn (2001) has pointed out that a lack of a prior intention to learn a word while reading does not exclude the possibility of learners directing attentional resources to processing a word. In fact, researchers generally agree that acquisition depends on “the quality of information processing when an unfamiliar word is first encountered” (p. 258) and subsequently on the “quantity and quality of rehearsal” (p. 258) in working memory as the word is processed.

Laufer (2003) explains why reading a text for meaning may not trigger the cognitive processing mechanisms essential for word learning. For example, noticing (Schmidt, 2001) a new lexical form or a new meaning for an already familiar word form is generally considered a prerequisite for establishing a form–meaning connection to be stored in memory. As L2 readers focus on comprehending a text, they may fail to notice a new word form or meaning because they are able to comprehend the idea without understanding each word. Likewise, learners may fail to understand the word in its context, skip it, and thereby fail to acquire its meaning. At the same time, learners may not realize that a word’s meaning is unfamiliar when encountering polysemes (a word that has multiple meanings) and homonyms (a word that sounds and is spelled the same as another word but has a different meaning) of words they already know. For example, polysemes require conceptual understanding of conventionalized expressions (e.g., the meaning of “break”: *He broke his leg*; *Who broke the news* [announce]?; *He broke his promise* [failed to keep]; *He broke yet another record* [improved]), whereas homonyms require the ability to differentiate between contexts (e.g., a file: used to put papers in, or a tool). However, even if L2 readers notice a new word, they may not be able to infer the correct word meaning because the context does not provide sufficient clues; the readers do not have the relevant background knowledge necessary to infer the meaning, or they end up inferring an incorrect meaning because they do not understand the context well enough.

Rott (2007) has further pointed out that processing a text for its meaning and processing a word to be retained in memory may involve different cognitive mechanisms. If both processes draw on the same limited pool of processing resources, they might be in conflict. That is, shifting attention to individual words may interfere with text comprehension, while a lack of attending to specific words may hinder lexical retention. Additionally, L2 learners may have to encounter words repeatedly in order to learn them (e.g., Horst et al., 1998), a requirement which seems unlikely in an instructional learning environment where exposure to the target language is limited to course materials.

Lexical Intervention Tasks

Addressing the shortcomings of an uninstructed reading-based approach to vocabulary acquisition, researchers have been exploring lexical intervention tasks to ensure that learners notice specific words and process the correct meaning. Although the majority of lexical intervention studies have been based on reading as a source for learning, a few have started investigating oral input or interaction tasks. The main goal of classroom-based investigations has been to identify task characteristics that explain why some interventions are more effective for long-term word retention than others. The majority of these investigations were conducted in an information-processing framework, sharing the assumption that

superior word acquisition and retention depend on a deep level of processing. Craik and Lockhart (1972) postulated that processing the meaning of a new word leads to a deeper level of processing as compared to processing a word's phonological form. Other researchers have emphasized the effectiveness of a more elaborate encoding of words through rich associations of multiple word aspects, such as the processing of spelling, pronunciation, grammatical category, basic meaning, and collocational aspects (see Hulstijn, 2001). Multimedia based studies have further stressed the encoding of multiple word representations at the semantic, pictorial, and phonological levels (e.g., Mayer, 2001).

Rott (in press) categorizes these intervention tasks as follows:

1. Enhancing the noticing of hitherto unfamiliar words and thereby foster the processing and learning of these words. Typically the assignment of the correct word meaning is enhanced with L1 translation, L2 synonym, multiple choice, and pictorial types of glosses provided in the margin of the text;
2. Increasing the frequency of exposure to new words to increase the chance that an initial memory trace is retained. Consequently, additional word aspects can be acquired during subsequent encounters with the word;
3. Training word inferencing strategies to foster correct meaning assignment;
4. Providing access to a dictionary, concordance (electronic list of word occurrences with the immediate contexts), or other multimedia resources to process form–meaning connections elaborately and to learn the context-specific meaning of a word;
5. Supplying post-reading vocabulary activities to ensure the processing and rehearsal of words;
6. Using output activities at the sentence or discourse level to trigger the noticing of a lexical gap, enhance the processing of the word's meaning, and foster a deeper level of processing and rich associations;
7. Encountering input texts that are either simplified or elaborated by the researcher to foster the noticing of words. Likewise, providing opportunities to clarify the meaning of words during partner activities results in reflective language usage and modified output.

While some studies compared the effect of the intervention task on word gain to a control condition that did not receive any word enhancements, others compared the effect of different interventions by manipulating the quality and quantity of word processing. Moreover, the interventions vary greatly. Some interventions are more obtrusive (e.g., by requiring learners to use the word to be learned) and others are less obtrusive (e.g., such as the provision of glosses). Some are used while completing the main task (reading, writing, listening, interaction), others are completed afterwards. As these studies vary greatly in set up and procedures, findings do not provide definitive guidance as to which lexical interventions are more effective. And a cohesive account of how to transfer research results to the language classroom has been missing.

Recent Developments

In an effort both to provide guidelines for materials design and to determine the instructional value of lexical intervention tasks, Laufer and Hulstijn proposed the construct of task-induced involvement in order to “operationalize general constructs such as noticing, elaboration, motivation, or need, at the micro level of learning tasks” (2001, p. 9). The motivational-cognitive construct of involvement entails three components: need, search, and evaluation. Each of these three components can be present or absent when processing

4 INCIDENTAL VOCABULARY ACQUISITION

a new word. Initial investigations (e.g., Hulstijn & Laufer, 2001) have not been conclusive about the generalizability of the construct to all tasks at all language levels.

Moreover, more recent studies on the effect of extensive reading suggest that previous studies underestimated incidental word acquisition. Longitudinal case studies which tracked students' full and partial word gain (e.g., Pigada & Schmitt, 2006) suggest that partial word gain measures are essential to assess the effectiveness of reading. Establishing a memory trace during an initial encounter with a word can be filled in during subsequent encounters and reduces the learning effort necessary to retain the word long-term. Likewise, the use of corpus technology, which allows the collection of topic, genre, or modality specific texts, not only provides students with individualized reading materials but also offers the individualized assessment of word acquisition (Horst, 2005).

Finally, many L2 researchers agree that at the initial L2 learning stage large quantities of words (2000–3000 word families) can be learned effectively with intentional word-learning exercises. After learners have established a large enough lexicon to read more fluently, researchers recommend that instructional programs should be expanded to include extensive reading opportunities (e.g., Nation, 2001).

Indigenous Languages in the 21st Century

TERESA L. MCCARTY

The world's 370 million Indigenous people represent 4% of the global population but speak 60 to 75% (4,000–5,000) of its languages (UNESCO, 2005). The contexts in which Indigenous languages are spoken range from that of Quechua, spoken by 8–12 million people in six South American countries, to Sámi in Scandinavia where five of 10 original languages are used as mediums of instruction in three Nordic states, to the USA and Canada where more than 200 Native languages are spoken—nearly all highly endangered—to the Indian subcontinent with 84.3 million tribal people who speak several hundred mother tongues, to sub-Saharan Africa, where a proliferation of Indigenous mother tongues compete with a handful of powerful colonial languages for a place in school curricula. Uniting these diverse sociolinguistic contexts and peoples is a history of colonization, physical and linguistic genocide, and deterritorialization. Language education policy has long been a primary tool for wielding colonial power and a principal means of linguistic and cultural assimilation. At the same time, recent decades have witnessed the rise of counter-hegemonic Indigenous movements focused on language and education rights. This entry considers the sociohistorical background for these movements and examines the language maintenance, revitalization, and revival initiatives they have spawned.

Sociohistorical Context

Despite a rich legacy of oral and written literary traditions and the presence of contemporary autochthonous literacies and education systems, Indigenous languages have been largely ignored and denigrated in Western and Western-modeled schooling—a common practice with regard to minoritized languages in the context of national schooling throughout the world. In sub-Saharan Africa, this occurred as European missionaries constructed an artificial multilingualism whereby closely related African varieties (similar to British and American English) were recorded as distinct tongues. These linguistic boundaries became the template for dividing African peoples territorially and for “de-Africanization” through the privileging of colonial languages for high-status purposes, including schooling (Makalela, 2005). In North America, from the 17th through much of the 20th century, Native children were forcibly removed from their families and compelled to attend distant residential schools where “no Indian talk” was a cardinal rule (Spack, 2002). During the same period, Australian Aboriginal and Torres Strait Islander children, known today as the “stolen generation,” were forcibly taken from their homes to distant schools where they were prevented from learning their heritage language and suffered physical and emotional abuse. Similarly, in Nordic countries Sámi children were punished for speaking their language in school (Magga & Skutnabb-Kangas, 2003). In Latin America, centuries of segregated schooling aimed to purge Indigenous languages as part of the colonial project of building monolingual/monocultural national identities (López, 2008).

Mother-tongue schooling is still denied to millions of Indigenous children, with both individual and societal consequences. In the USA, American Indian and Alaska Native

students are 73% more likely to be placed in remedial education programs, often on the basis of linguistic differences (National Caucus of Native American State Legislators, 2008). In both the USA and in Canada, colonial schooling has led simultaneously to the loss of Indigenous languages among children and to their stigmatization as “limited” speakers of the national language. In India, where only 26 Indigenous languages are used as mediums of instruction in the primary grades, a quarter of young children face severe challenges because their home language differs from the school language (Jhingran, 2009). In short, Indigenous children throughout the world are overrepresented on the negative side on all linguistic and educational indices (Skutnabb-Kangas & Dunbar, 2010). Moreover, the exclusion of Indigenous mother tongues from schooling creates what Mohanty, Mishra, Reddy, and Ramesh (2009) call a “vicious circle of language disadvantage” whereby Indigenous languages are considered inadequate for schooling, making them vulnerable to language shift and justifying further exclusion as mediums of instruction in school.

Contemporary Indigenous Movements for Linguistic Self-Determination

Recent decades have seen a significant repositioning of these power relations as a widespread Indigenous activism has taken hold. Throughout Latin America, policies promoting bilingual intercultural education (EIB) are commonplace (King, 2008; López & Sichra, 2008). In Norway, the 1987 Sámi Language Act makes Sámi and Norwegian coequal; a more recent Norwegian national curriculum reform marks the first time in the history of the Nordic countries that a Sámi-specific curriculum has held equal status with the national curriculum (Hirvonen, 2008). In the USA, the 1990/1992 Native American Languages Act and the 2006 Esther Martinez Native American Languages Preservation Act support ongoing language recovery efforts (Warhol, 2011). In Aotearoa/New Zealand, the Māori language has co-official status with English and New Zealand Sign Language (May, 2005). In post-apartheid South Africa, official language policy includes nine Indigenous languages and the option for children to be taught in the official language of their choice (Makalela, 2005).

At the international level, the United Nations in 2000 established the 16-member Permanent Forum on Indigenous Issues with a mandate to advise the United Nations on Indigenous issues relating to education, the environment, language and culture, economic and social development, health, and human rights. In 2007, the United Nations General Assembly approved the *Declaration on the Rights of Indigenous Peoples*, which includes provisions “to revitalize, use, develop and transmit . . . [local Indigenous] histories, languages, oral traditions, philosophies, writing systems and literatures” (2007, Article 13[1]).

These “top-down” policies and programs are complemented by a host of “bottom-up” or grassroots language education efforts worldwide (Hornberger, 2008). In a recent study of medium of instruction policies in Ethiopia, Heugh (2009) found that students who have the benefit of mother-tongue schooling for the full length of their primary schooling (eight years) perform as well as or better than their peers in English-medium classrooms on assessments of English, science, and mathematics. In the Indian states of Andhra Pradesh and Orissa, mother-tongue education in 1,495 schools and 18 Indigenous languages has improved student competencies in literacy and numeracy while increasing school attendance and enhancing school–community relations (Mohanty et al., 2009). In the south-western USA, long-term Navajo bilingual education programs have led to the “four-fold empowerment” of students, parents, Native teachers, and tribal education leaders (Holm & Holm, 1995). In Hawaii and New Zealand, Hawaiian- and Māori-medium education has enabled Indigenous children to achieve educational parity with their White peers while revitalizing these threatened mother tongues (Wilson & Kamanā, 2006; Hill & May, 2011).

Even in communities with “sleeping” languages—those lacking native speakers but with documentation and a living heritage language community (Hinton, 2001; Leonard, 2008)—bold language revival efforts are under way. In the USA, for instance, the Wôpanâak Language Reclamation Project is using the 1663 Eliot Bible and historic legal documents written by native speakers to restore language-learning opportunities for Wôpanâak heritage-language tribal nations, whose last native speaker died in 1908. The project has credentialed two Wôpanâak linguists, developed a 10,000-word dictionary, and created a “no English” curriculum for learners of all ages (Ash, Fermino, & Hale, 2001).

Summary and Future Directions

While the contemporary circumstances for Indigenous languages are highly diverse, they share the goals of self-determination and social justice. These efforts have produced impressive linguistic and educational gains. Yet they face ongoing challenges from the combined pressures of globalization, homogenization, and socioeconomic stratification (McCarty, 2003). In Indigenous communities, linguistic repression, racial discrimination, and economic injustice are enduring language-policy themes.

The sustainability of Indigenous languages entails the empowerment of their speakers. Moving forward into the 21st century, language planning and policies that promote self-determination and equity are prerequisites for the revitalization and maintenance of Indigenous mother tongues.

Indigenous Literacies

LYNN MARIO T. MENEZES DE SOUZA

Indigenous literacies are an important new area of research and discussion in applied linguistics marked by various controversies and issues of importance. These begin with the controversy around the concept of indigeneity. The term is generally used by those located in mainstream or dominant social groups, often within a context of former European colonization, to refer to minority and regional groups whose languages and cultures are considered to be restricted to small groups in isolated regions and to have historically existed prior to the mainstream or dominant (colonizing) culture(s) and language(s) within the same nation. As such, synonyms for the term *indigenous* include “first nations,” “aboriginal” or “tribal,” or even “amerindian.”

It is precisely because the term *indigenous* is used by those located in the dominant culture that many of the controversies around *indigenous literacies* arise. These begin with the very concept of *literacy*, which, like the term *indigenous*, originates in the values and knowledge systems of dominant Eurocentric cultures and is transferred, often unproblematically, to refer to the writing practices of the indigenous cultures.

Historically, if *writing* is understood as a means of recording or registering information and knowledge, this has often meant that forms of writing which originated and were practiced in so-called indigenous communities and which had no correspondence in the knowledge and writing systems of the dominant mainstream community were not even perceived or valued as writing. Examples of this include, in the Andes, the use of knots by the Incas in the *quipu* system and the use of designs woven into ponchos and blankets to record and register important cultural information (Howard-Malverde, 1997); in the Amazonian region the use of iconic markings on ceramics, wood, and skin were and are also used to register information (de Souza, 2006). Moreover, many of the so-called cave drawings encountered in various parts of the world are accepted as forms of registering and recording information (Brandão, 1937).

Located in dominant and often colonizing cultures, analysts of writing have tended to privilege and take for granted their own knowledge systems and have used them as a basis for evaluating nondominant, indigenous modes of writing. Thus Sampson (1987), Brotherston (1979), Munn (1973), and Mallery (1972), for example, in an analysis of different writing systems, consider nonalphabetic (“semasiographic” or “iconic”) writing systems to be less efficient and less developed than alphabetic writing systems. This conclusion is based on the assumption that alphabetic writing as a code that represents sound and voice is considered to be self-sufficient and nondependent on previous knowledge, permitting a text to be read by readers distant in time and space from the original writer and the original moment of the writing of the text. Thus, the assumption goes, texts written in previous centuries may be read and understood today and texts written by writers at a great distance from prospective readers may supposedly be sent and read with little or no difficulty for the readers.

However, what this assumption ignores is that reading and writing are not simply a matter of composing in or deciphering alphabetic codes, but are embedded in social practices (Street, 1984; Barton, Hamilton, & Ivanic, 2000) which greatly affect the forms that writing and reading take. A knowledge of the alphabetic code of one’s language is not sufficient to help a reader read texts embedded in social practices of which she is not a

2 INDIGENOUS LITERACIES

member or a participant. For example, if a reader is not familiar with the social practices of reading the legal, academic, or medical texts of her community, the mere knowledge of the alphabetic code of her language will not help in understanding such texts.

Thus it is that writing as a social practice involves a connection between the *representational codes* (used to represent sounds in the alphabetic system) and the *knowledge system* of a particular community or culture. Furthermore, the fact that analysts often take their own codes and knowledge systems as yardsticks for perceiving or judging the existence, lack, or deficiency of writing systems of indigenous communities indicates a connection between *power* and writing systems. The result of this connection between power and knowledge is that the systems of the dominant (in which the analysts and policy-makers are generally located) are taken as the unquestionable measures against which nondominant indigenous practices are measured (see Mignolo, 1995 for a discussion of the knowledge and power collusion).

This connection between writing, knowledge, and power in indigenous literacy is particularly noticeable in the difficulty many analysts in dominant cultures have to perceive and value nonalphabetic, *visual* forms of indigenous writing. Analysts such as Derrida (1974) have pointed to how in dominant Western cultures knowledge is believed to be represented and expressed through *speech* and recorded in *alphabetic* writing as a representation of speech. Derrida refers to this as *phonocentrism* where voice and speech are privileged as vehicles of knowledge and recorded on paper as alphabetic writing.

In some indigenous cultures, such as many of those of the Americas and Australia, it is not voice but *vision* (in some cases both vision and voice) that is considered to be the *source of knowledge* (de Souza, 2008). In these cultures, knowledge originates in ways of seeing such as dreams or visions (Benedict, 1922). Just as in *phonocentric* cultures, these vision-based cultures also register and preserve their knowledge by writing it down on a material base such as wood, textiles, ceramics, or stone, as we have seen above.

However, as knowledge is not deemed to be primarily expressed through voice but through *vision*, the means of recording this knowledge is *visual* and not sound-based or alphabetic. Thus the knowledge is recorded as it is thought to have been seen, *visually*, in the form of *drawings*. And as writing is a form of social practice and therefore ruled by convention, this visual writing, far from being arbitrary and individualistic, will depend on and follow the community's preestablished conventions for visual representation, varying from figurative representational forms to more abstract, nonrepresentational forms (de Souza, 2003).

Unfortunately, considering that in dominant Eurocentric alphabetic communities "drawings" are considered to be decorative and secondary to alphabetic writing, and moreover, as a result of the power-knowledge-writing connection, it is not uncommon for forms of indigenous visual writing to go unnoticed or to be considered by analysts and policy-makers as mere doodles of distracted individuals of nonindigenous dominant groups. This in turn results in the belief of the dominant community that these indigenous communities have no forms of writing of their own. Given the Western *phonocentric* belief that knowledge is represented through alphabetic writing, and coupled with the belief that the only developed form of writing is alphabetic, it is not uncommon for this to result in an unvoiced assumption that these indigenous communities have no knowledges of value. This in turn generates so-called "developmental" policies for not only making these indigenous communities literate in alphabetic writing, but also for supplying them with the knowledges they are deemed not to have.

Policies of indigenous literacy and education often aim well meaningly at eliminating these alleged deficiencies of indigenous communities, but often generate or perpetuate complex conflicts between indigenous and dominant concepts of knowledge, language, and writing.

The conflicts of language which arise in issues of indigenous literacy are generally of two main and interconnected types: the phenomenon of bilingualism and the concept of the “standard” language.

In some societies, such as Brazil, it was common in policies of indigenous literacy education to assume that indigenous communities should be made *initially* literate in the local indigenous language and subsequently made literate in the dominant national language. The ideological mainstay of these policies was to assimilate indigenous communities to the national language and culture.

Given the difficulty in perceiving the nonalphabetic visual forms of literacy already existent in these communities, this dominant policy assumed that these communities should first be made (alphabetically) literate in their own, indigenous languages. It was assumed that this would preserve previously unwritten indigenous languages and value indigenous cultures and knowledges. However, as these languages were not written, alphabetic scripts had to be developed and, more significantly, a *standard* written form of the indigenous language had to be created.

Curiously, it is probable that the concept of a fixed standard language, like the concept of a fixed systematic grammar, is the complex *consequence* of generations of using writing in a literate culture and probably not the *origin* of such a culture. Yet linguists have not hesitated in producing standard forms of indigenous languages in nonliterate cultures for the purposes of literacy teaching. The standard form of the indigenous language in question would be based on abstract linguistic notions of system and standard (originating, let us not forget, in the dominant, nonindigenous knowledge systems), with little or no regard for the conflicts and discrepancies these may cause in indigenous knowledge systems. In the case of Brazilian indigenous cultures, for example, the concept of a neutral, universal norm, be it of language or knowledge, is completely alien to their knowledge systems, which privilege forms marked for the *perspective* of speakers and knowledge producers. This means that rather than neutrality, universality, and normativity, these cultures privilege contextually marked and locally valid forms of language and knowledge (de Souza, 2006). The concept of a “standard” whose value/meaning is considered to be stable and unchangeable for all users, independent of context and speaker, is alien to these cultures and yet they are expected to accept and use such a concept in their everyday uses of writing in their “own” indigenous languages.

Once again the power factor and inequality predominate in indigenous literacy (see, e.g., Grossman, 2006 for a discussion of a related secret/sacred conflict in Australian indigenous cultures).

In these official policies for indigenous literacies, once established, the alphabetically standardized form of the indigenous language is taught until literacy skills are considered to have been developed. However yet again, attention should be called to the concept of literacy being presupposed in such policies. If it were indeed a policy that conceived of literacy as *social practice*, then it cannot merely teach *how* to use the indigenous written language which has never been used in the community; it has to ironically and simultaneously *create* a social practice in the community for the use of the new alphabetically written indigenous language. As we have seen, this invented practice may cause serious conflicts with the existing knowledge systems of the indigenous community (de Souza, 2006) and may detrimentally affect them.

Moreover, it may create in newly literate indigenous readers a complex sense of deficiency of available knowledge in the written indigenous language. When this is coupled with the subsequent teaching of literacy in the dominant national language and the wealth of available resources in this nonindigenous written language, indigenous learners may indirectly be being taught how “deficient” their own language and culture are.

4 INDIGENOUS LITERACIES

A final important issue in indigenous literacy is the orality/literacy debate. In light of the now widely accepted rejection of the “great divide” (Street, 1984) theories which separated societies into oral and literate and showed that all societies possess elements of both literacy and orality, it is worth remembering that many indigenous communities which have been submitted to influences from and/or contact with dominant alphabetic cultures may manifest juxtaposed or coexisting multimodal forms (Finnegan, 2002) and practices of literacy, which interweave oral, written, and visual elements. These may be forms which not only *preexisted* the influence of alphabetic literacy, such as the already mentioned forms of *visual* literacy, but may also appear as new, hybrid forms of writing. Examples include 19th-century North American Plains Indian ledger drawings (see plainsledgerart.org), Australian aboriginal dot painting (Johnson, 2007), papunya, or Brazilian Amazonian *kene* writing (de Souza, 2003). In all these cases, new material artifacts, such as pencils, paper, colors, paints, and so on, were introduced into the indigenous culture through contact with the dominant culture and resulted in new forms of nonalphabetic writing-as-registration-of-knowledge, previously nonexistent in both the indigenous and the dominant cultures, but which portray characteristics of both: indigenous visuality and the use of nonindigenous paper and writing implements.

Thus a critical issue in dealing with indigenous literacies is for the analyst to be constantly self-consciously and self-critically aware of her cultural presuppositions in terms of knowledge, language, and writing and how these are deeply embedded in an alphabetic, phonocentric, literate culture. Being unaware of this may not only impede the prospective analyst’s understanding of indigenous literacy practices which are distant from and dissimilar to dominant nonindigenous practices, but more seriously may unwittingly also continue to treat indigenous cultures and peoples as deficient, unequal, and inferior.

Individual Differences in the Classroom

TIM MURPHEY AND JOSEPH FALOUT

Introduction

Individual differences (IDs) is the notion that each individual person comprises a unique combination of aspects that might determine learning outcomes. The traditional focus depicts these aspects as fixed traits (e.g., personality types or learning preferences) that are often measured through scale-based surveys and linked by statistics to other traits or to outcomes-based dimensions (e.g., proficiency). Recent, emerging understandings instead view IDs as socially interdependent, malleable states developing over time. To describe these dynamics, research methods are also expanding. This entry draws from emerging epistemologies such as dynamic systems (Ushioda), poststructuralism (Norton), and socio-cultural anthropology (Rogoff). Most of the research cited below is the authors' own and has been conducted in Japan with adult learners of English as a foreign language (EFL). This selection contrasts with much research on IDs being conducted in Europe, North America, and other Western contexts for EFL, and which is often focused on young learners and on learners from bilingual and bicultural societies.

Some IDs are dynamically emerging amalgamations of motivations and identities through time, depending upon the emotional-cognitive and situational states of individuals and groups, interacting in complex and chaotic sociocultural and sociohistorical systems. We discuss the co-constructed malleable unity of past, present, and future selves (identities) in learning communities and how many IDs emerge, mediated by (a) perceptions of past events, (b) present group dynamics and the mutual influence of participants, and (c) the plans, goals, and dreams stimulated by our imagined communities and possible selves. What might matter more for learning is not *what* learners experience as much as *how* they perceive and react to their experiences; how they internalize their positive and negative experiences in relation to their academic self-concept, cope in their thoughts and behaviors, engage in learning through their self-regulatory capacities, and how their learning theories about themselves determine future action (Dweck, 2000). Rogoff (1995) writes, "Any event in the present is an extension of previous events and is directed toward goals that have not yet been accomplished. As such, the present extends through the past and future and cannot be separated from them" (p. 155).

While traditional research shows how the past influences the present and future, research on possible selves (Markus & Nurius, 1986) and imagined communities (Norton, 2001) allow us to see how future projections change present action as well. Figure 1 depicts a person operating in three planes of time simultaneously, in which any one plane can become more consciously dominant depending upon the dynamics of the circumstances. The past may continually influence the present through the antecedent conditions of the learner (ACL); near peers in present communities of imagination (PCOIs) (Murphey, 2008) can mutually influence perceptions of the past, present, and future and become models for one another (Murphey & Arao, 2001); and possible selves and imagined communities are products of our possible pasts and presents. These influences emerge through the

2 INDIVIDUAL DIFFERENCES IN THE CLASSROOM

Figure 1 Three overlapping mind times situated in emerging contexts © Tim Murphey and Joseph Falout

meaning making of individuals and groups rather than through predetermined rules. This resonates with Ushioda's (2009) "person-in-context," capturing "the mutually constitutive relationship between persons and the contexts in which they act—a relationship that is dynamic, complex and non-linear" (p. 218). Therefore, to consider IDs is to consider the complex system of interdependent interactions of individuals in the specific local community of practice, our everyday classrooms.

Knowledge of antecedent, present, and future conditions of the learner can offer teachers and researchers valuable information about students' IDs that significantly impact their learning and their behavior in classes. While we need to increase the ways we find out and use such information, we already know that using, for example, language learning histories (Murphey & Carpenter, 2008) and surveys can inform us about ACLs; journaling, action logging, and newsletters (Murphey, 1993) can inform us about present conditions from the students' perspectives; and certain activities, such as imagining a 10-year class reunion or constructing a possible selves tree, can help students imagine and aim for future desired conditions. Teachers are inviting the development of students' thinking when focusing attention on these times and topics, which should help students to construct meanings about their learning lives that help them better cope with the past and present to project more healthily into the future. We recommend enlisting students as coresearchers in such activities to increase their own sense of agency in the meaning making of the past, present, and future, as they learn from each other's IDs and stimulate greater willingness to communicate in the group (Murphey & Falout, 2010).

Antecedent Conditions of the Learner

Learners' histories merge into present psychological states called the ACL, which are carried into new academic situations (Gorham & Millette, 1997). These factors can include

self-efficacy, expectations of success, attributions of success or failure, task value, goal orientation, and self-concept. They are malleable through social interaction and dependent on task-specific activity. Therefore ACLs are not set traits; they are fluctuating and adaptable emotional-cognitive states, mediated by specific social environments which influence outcomes.

The construct of ACL has been applied to studies in motivation and second language acquisition. In Falout and Maruyama (2004), learners experiencing a streak of negative affect toward learning English had concurrent losses in motivation through exposure to monomethodical teaching, lack of progress, and loss of self-confidence, ending up with lower proficiencies and more negative ACLs than learners who had longer periods of positive affect, who had higher proficiencies and more positive ACLs. Falout, Elwood, and Hood (2009) confirmed that affective states and self-regulatory capacities correlated with proficiency outcomes, whereas frequency of demotivational experiences did not, indicating that ACL could be a predictor of learners' future possible selves. There was evidence that the number of times learners had negative experiences was irrelevant, but that learners who could control their affect and behaviors about learning English became more proficient and reported higher ACLs. Such learners displayed more frequent use of self-regulating behaviors when struggling with learning English.

Carpenter, Falout, Fukuda, Trovela, and Murphey (2009) investigated how learners with different ACL levels lost and regained their motivation. Figure 2 shows that those with higher positive ACLs reported earlier remotivation by using motivational and metacognitive learning strategies in greater types and frequencies, and were influenced positively by significant others in their social environment for becoming remotivated to learn English. For instance, high positive ACL students were more diligent with tasks, both self-regulated and teacher-regulated, alongside taking short breaks to recharge their energy to study. Negative ACL learners showed a lack of abilities and learning strategies in greater types and frequencies to regain control and self-confidence after setbacks, displaying a tendency toward isolated, helpless states.

The salient difference among these learners was their self-appraisals in relation to academic experiences. ACLs provide useful information about IDs that teachers can use to design activities that might help students develop more holistically, activities that are done in a PCOI and lead to positive possible selves.

Figure 2 In-class motivation time lines © Tim Murphey and Joseph Falout

Present Communities of Imagination, Imagined Communities, and Possible Selves

Students also have IDs concerning their ability to collaborate with their present group and conceptualize their futures. Norton (2001) introduced the concept of *imagined communities* in language education to explain different patterns of learners' investment in learning their target language. Imagined communities are groups we think we belong to but whose members cannot be known with certainty. Researchers since Norton have shown that students' investments in learning greatly depend on their beliefs, the type of their imagined communities, and their propensity to envision possible selves. All these are mediated by socializing with near peer role models (Murphey & Arao, 2001) in their PCOIs.

Fukada's (2009) quantitative analysis of 248 university student surveys found a strong correlation between the extent of out-of-class autonomous learning activities and their imagined communities—students who were not active out of class reported not imagining strong imagined communities while those who were active had strong and more specific imagined communities.

When classes engage in activities concerning students' pasts or future projections, they do so within their PCOIs, the resources within present groups, enriched by near peer role modeling, positive emotional contagion, and good group dynamics which create nurturing communities of practice and co-constructed imagined communities and possible selves. Murphey and Carpenter (2008) showed how students were able to remember seeds of agency in their past language learning histories, share them in the present, and inspire each other to act more in the future. When individual approaches and thoughts about learning tasks, second language socializing, and futures are shared in a second language class as course content, students can become more hopeful, with pathways thinking and agency thinking, and stimulate more willingness to communicate.

Inference

JAMES DEAN BROWN

Using Inferences in Quantitative Research

An *inference* is a conclusion or implication that results from examining evidence or using logic, and *inferring* is the process that leads from the evidence or logic (or both of these) to the conclusion or implication. In quantitative language studies, researchers make inferences: (a) about constructs from variables, (b) about populations from samples, and (c) about probabilities using inferential statistics.

Drawing Inferences About Constructs From Variables

The key to understanding how researchers draw inferences about constructs from variables is to first understand three terms: constructs, operationalization, and variables. Once these terms are clear, understanding the relationships among them will clarify how inferences about constructs are drawn from variables.

The *constructs* of interest in language research are typically things that go on in the human brain. For example, the construct *language proficiency* is primarily a mental process. Other constructs include mental attributes such as motivation, anxiety, learning strategies, extroversion, and so forth. Such constructs, more precisely known as *psychological constructs*, are the central theoretical concepts that are typically being studied in language-learning research, because they are viewed as important psychological characteristics or traits operating in the participants' brains that might be related in important ways to language learning (which is itself a construct).

Unfortunately, researchers cannot observe psychological constructs directly because constructs happen inside learners' brains. Instead, researchers *operationalize* constructs, which simply means that they devise ways to measure or otherwise observe and quantify the constructs. For example, the Modern Language Aptitude Test (MLAT) is sometimes used to operationalize the language aptitude construct. Study participants answer questions on the MLAT, which are scored; the scores are then used as numerical definitions of the construct (i.e., the language aptitude construct is operationalized) such that, relatively speaking, a person with a high score has a lot of language aptitude and a person with a low score lacks language aptitude; these numbers are then used as a language aptitude variable that is studied statistically. The measures used to operationalize constructs and form variables can take the form of tests, questionnaires, countable observations, etc.

Variables are things that typically vary among people or over time. Language researchers focus on and manipulate variables when they do research. Variables can be operationalized constructs such as language aptitude, motivation, and pragmatics ability. But researchers may also be interested in studying the effects of gender, age, nationality, text types, etc., each of which can typically be established as a variable by simple observations, even though they are not constructs.

The key to understanding the relationships among constructs, operationalization, and variables is to realize that there is a big difference between a theoretical construct that is being investigated and the numbers derived from some measure of that construct, which are used to operationalize that construct as a variable. For instance, if the construct is

2 INFERENCE

language aptitude and the MLAT is used to operationalize that construct, then the MLAT scores serve as a numerical representation of a student's language aptitude. However, at best, such operationalizations are indirect reflections of the constructs involved and are not the constructs themselves, much like Plato's allegory of the shadows cast by the fire on the cave wall: we can never see the shadows directly, but we infer from the reflection what the shadows represent. Similarly, we can never see a psychological construct directly; we can only *infer* from the operationalized variable that it is present and how strong it is.

Clearly, the links among constructs, operationalization, and variables are inferences and not absolute one-to-one correspondences. Hence, these links must be supported by convincing arguments. Presenting such arguments is the researcher's responsibility but peer reviewers and, ultimately, the readers of language studies must judge whether researchers have presented convincing arguments for their inferences.

Drawing Inferences About Populations From Samples

Language researchers also make inferences about populations based on what they find in samples. *Samples* are subsets of participants (or other countable objects) drawn from some larger population in such a way that the subset can be said to represent the larger population. Researchers use samples to minimize the amount of effort and resources needed for their research.

In contrast, a *population* is the entire group of people that the researcher is interested in. For example, a researcher might be interested in the entire population of students studying Korean at the University of Hawaii (UH) or all the texts in Turkish language newspapers. A population needs to be well defined and described if sampling from that population is to work well and lead to correct inferences about the population. However, in some cases, clearly defining and describing a population can be surprisingly difficult. For instance, imagine trying to define and describe the population of all ESL students in the United States. In cases like this, researchers typically shift their interest to a target population that *can* be defined and described more narrowly, such as all the ESL students at the UH. In the process, the inferences that can be made (i.e., the degree to which the results can be generalized) by sampling from the population are considerably circumscribed to that narrower population of ESL students at UH.

If *sample data* are adequately selected (i.e., the sample is truly representative of the population), then the researcher can make the inference that the results based on the sample should also be representative of results that would be obtained if the researcher studied the entire population (with a certain probability or within a certain range of error). The adequacy of such inferences will depend on how well the population is defined, how adequately the sample represents the population, how well the sampling technique serves the purposes of the research, and how large the sample size is (both in absolute terms and relative to the population size). For example, a sample of 100 Turkish newspapers could be randomly selected from a list of all newspapers in Turkey and then one editorial could be randomly selected from each newspaper. If that procedure meets the needs of the research and the sample size is deemed large enough, the sample could arguably be said to represent the population of all the editorials in Turkish newspapers.

Drawing Inferences About Probabilities From Inferential Statistics

Statistical inferences involve "using probability and information about a sample to draw conclusions (inferences) about a population or about how likely it is that a result could

have been obtained by chance" (Vogt, 1993, p. 220). Generally, these two purposes are called *estimation* and *hypothesis testing*.

Formally, *estimation* is concerned with drawing inferences from a sample about the mean, standard deviation, and so forth, of a population. Procedurally, such estimation is done by calculating statistics to estimate parameters. *Statistics* are numerical indicators that most often describe the central tendency and dispersion of sets of numerical data in samples. Common statistics of central tendency are the mean, mode, median, and so forth, and common dispersion statistics are the range, standard deviation, semi-interquartile range, and so on. (Statistics are usually symbolized with roman letters, e.g., the sample mean = M ; the sample standard deviation = SD). *Parameters* are analogous numerical indicators of central tendency and dispersion *in the population*. Parameters are usually symbolized with Greek letters (e.g., the population mean = μ ; the population standard deviation = σ).

Statistics are used to estimate *parameters*. Or put another way, parameters are inferred from statistics. Thus, when researchers describe the distributions of numbers in their studies with statistics, the notion that these statistics are most often estimates of analogous parameters in the population should always be on the minds of researchers and readers alike.

Formally, *hypothesis testing* is "the branch of statistical inference concerned with deciding between two (or sometimes more) hypotheses about some aspect of a distribution, such as the mean, median, variance, shape, etc. for the population of interest to the experimenter" (Yaremko, Harari, Harrison, & Lynn, 1986, p. 96). Put another way, hypothesis testing is a way of drawing inferences about the probability of a particular result being obtained by chance alone. *Inferential statistics* are used for this purpose. Common inferential statistics include t tests, F ratios, chi-square values, and so forth.

When a t test is applied, the hypothesis is about the probability that the difference between two means occurred by chance. For instance, a researcher might arrange for two randomly assigned groups of students to get six months of intensive French language training: a treatment group (one that got intensive *method X* training) and a control group (one that got intensive *traditional* training). The researcher gives an overall French proficiency test to both groups after the treatment and wants to know if the mean for the treatment group is higher than the mean for the control group. Since two means are only very rarely *exactly* the same, even if they are based on random numbers, the researcher finds that the two means are different. However, it is important to consider whether the difference between the two means is just a chance occurrence or could be due to the difference between method X and traditional language training.

Starting from a neutral stance, the researcher proposes a *null hypothesis*, that is, that the means of the two groups are the same (or vary from each other only by chance). Given the researcher's theoretical reasons for designing the study, a reasonable *alternative hypothesis* would be that the mean of the treatment group will be higher than the mean for the control group. However, another alternative hypothesis would be that the mean of the control group could be higher than the mean for the treatment group. To sort this out, the researcher could compare the two means using a simple t test. If the t test turns out to be significant at say $p < .01$ and the mean for the treatment group is higher, the researcher can reject the null hypothesis and conclude that there is only a 1% likelihood that the observed difference between the means occurred by chance alone. Because the mean for the treatment group was higher than the mean for the control group, the researcher accepts that alternative hypothesis and infers from all of this that method X treatment worked significantly ($p < .01$) better than the traditional language training. How much better method X worked is a separate issue, but that can be determined by examining the magnitude of the difference between the two means. In any case, based on the probability found above, the researcher can be very certain that the resulting mean difference was not just a chance fluctuation.

4 INFERENCE

Typically, F ratios are used to make similar means comparisons when more than two means are involved. Correlational analysis involves examining whether a correlation coefficient observed in a study differs from the correlation that would be expected to occur by chance alone. A chi-square analysis involves investigating whether the observed frequencies in a study differ from the frequencies that would be expected to occur by chance alone. And so forth. The details of the hypotheses being tested and the procedures being followed vary considerably from inferential statistic to inferential statistic, but the nature of the inferences is always similar: that is, deciding between two or more hypotheses, starting with some version of a null hypothesis (of no mean difference, no correlation, no difference between observed and expected frequencies, etc.).

Conclusions

Clearly, inferences play an important role in quantitative language research. Researchers commonly use variables to make inferences about constructs, use samples to make inferences about populations, and use inferential statistics to make inferences about the probabilities that observed statistics did not occur by chance alone. In fact, most quantitative studies involve the entire three-part chain of inferences just described. Researchers and the readers of research must pay special attention to deciding if each of these inferences is sound and if the three types of inferences taken together form a cogent overall argument. If any link in this chain turns out to be weak, the overall structure of the study is threatened. Put more strongly, if the inferences in a study do not make sense separately or together, the study should probably be rejected by reviewers and ignored by readers.

Inference and Implicature

MICHAEL HAUGH

Inference Versus Implicature

An implicature is a type of speaker meaning that goes beyond what is literally said. Inference, in contrast, refers to the cognitive processes by which participants figure out meaning beyond what is said. Consider the following conversation:

Bart: Dad, Mom's spending more time at Moe's than you are.
Lisa: They seem awfully chummy.
Homer: Just what are you inferring?
Lisa: I'm not inferring anything. You infer, I imply.
Homer: Well that's a relief.
("Mommie Beerest" in *The Simpsons*, Price & Kirkland, 2005)

In this example, Bart and Lisa can be understood to be implying that Marge (Homer's wife) might be having an affair with Moe. This latter proposition counts as an implicature, and it is drawn through a process of inference. Homer, being Homer, next commits the classic mistake of conflating implicature with inference, to which Lisa responds with the well-worn dictum that speakers imply, while hearers infer. Dispute about the distinction between implicature and inference, however, is not restricted to popular discourse. On the one hand, many scholars view implicatures as if they can be treated as essentially synonymous with (nonlogical or pragmatic) inference (Sperber & Wilson, 1995; Levinson, 1983, 2000; Carston, 2002). On the other hand, other scholars insist that assimilating implicature to inference constitutes a conceptual and analytical error (Horn, 2004; Bach, 2006). Horn (2004) contends, for instance, that "speakers implicate" and "hearers infer" (p. 6). It is important to note, however, that this dictum rests on the technical notion of *implicate*, which is speaker-intended. It is thus not synonymous with the folk notion of *imply*, which involves meaning beyond what is said that is not necessarily speaker-intended, but rather may arise from the words themselves or how a hearer might normally interpret such words. On this latter view, then, while implicatures may be ascertained through inference by hearers, they are ultimately determined by the speaker's intentions.

There is reason to suspect, however, that Homer might not be entirely wrong in inadvertently mixing up what is implied with inference. Indeed, his claim that Lisa (and Bart) are inferring something here is actually correct in two senses. Both Lisa and Bart have inferred from their mother's recent behavior (e.g., spending a lot of time with Moe, getting on very well with Moe, and so on), along with real-world knowledge about how affairs involving married partners normally arise, that she might be having an affair with Moe. And they have also presumably inferred that, if they raise this behavior with their father, Homer might come to the same conclusion about the possible implications of Marge's behavior. Inferences are involved not only in interpreting what is said (by others and oneself), but also in recipient design, that is, the cognitive processes whereby we bear in mind the possible interpretations of, or effects on, our audience when producing an utterance. Inferences are not only made by hearers, then, but are in fact made by all participants in interaction.

DOI: 10.1002/9781405198431.wbeal0535

The underlying assumption that implicatures are determined by speaker intentions is not entirely correct either, despite Lisa's implicit claim to the contrary. In various types of literary texts, such as poetry, for instance, the writer may intentionally leave the choice of possible implicatures open for the reader. And in interaction, speakers may be taken to be implying something that is contrary to their intention (so-called "unintended implicature"), or they may intentionally leave the interpretation of what has been implied open to the hearer. While Grice anticipated such issues in originally reserving the term "implicature" to refer to an intentionally conveyed meaning in addition to what is said (thereby restricting it to the speaker), and proposing the term "implicatum" to refer to the product of this process (which thus arises from inferences drawn by either the speaker or the hearer), this distinction was gradually obscured in later writings (Haugh & Jaszczołt, 2012). Undermining the classic dictum that "Speakers implicate, hearers infer," then, is the realization that implicature is not restricted to the domain of speaker-(intended) meaning, but can also arise as a joint meaning at the level of discourse.

However, while the straightforward association of implicature with speakers and inference with hearers has been recently questioned (see Horn, 2012), the more fundamental distinction between implicature as a species of meaning and inference as a kind of cognitive process (or product) nevertheless remains. The key difference between the two is that, while speakers can be held interactionally or morally accountable for implicatures, neither speakers nor hearers are held accountable for all the inferences they make when participating in interaction, unless they display such inferences through saying or implying.

Types of Implicature

An implicature is commonly conceptualized in pragmatics as a form of speaker-intended meaning that arises in a principled way from the cooperative principle and conversational maxims through defeasible inferences. It is also generally claimed that two different types of implicature can be distinguished on the basis of the distinction between conventionalized reasoning across contexts (default inference) and once-off reasoning in particular contexts (nonce inference). The former can be termed default implicatures, while the latter can be termed nonce (or particularized) implicatures, with a further distinction possible between default implicatures that arise across all contexts unless otherwise cancelled (generalized implicatures), and those that only require a minimal context in which to arise (short-circuited implicatures). In the following excerpt from a recording of a telephone conversation between friends, for instance, we can observe examples of both default and nonce implicatures.

(1) WSC: DPF006: 0:18

18 C: Whadaya doing tonight?

19 S: I dunno, what are you gonna do?

20 C: Oh I've been invited to a party that I don't wanna really want to go to.

21 Hope to find an excuse.

22 S: Oh right. I see.

23 Um, haveya seen Lethal Weapon?

Cameron's initial question, "Whadaya doing tonight?" (line 18), is in the form of a standard preinvitation (Schegloff, 2007, p. 129). In other words, in a minimal context, namely, two friends talking on the phone, the speaker normally implies through this utterance-type that he/she is going to subsequently invite the recipient to do something together if the preparatory condition that has been invoked is met (i.e., that the other person is available).

Steve orients to this possible invitation (and thus the default implicature, more specifically, a short-circuited implicature) by inquiring about what the invitation might involve (line 19). This default implicature, however, is suspended by Cameron's next turn when he outlines the preparatory conditions for another kind of invitation, namely, an invitation from Steve (lines 20–1), thereby implying that he would like Steve to invite him somewhere (and so provide the means by which he can be excused from going to a party he doesn't want to attend). This latter implicature through which Cameron solicits an invitation from Steve arises from specific contextual information, and thus it counts as a *nonce* implicature. The change in Steve's understanding of the upshot of Cameron's prior utterance in line 18 in light of this qualification (in lines 20–1) is evident from his use of "oh" and "right" (line 22), by means of which he receipts "new" information and understanding respectively (Heritage, 1984; Schegloff, 2007, p. 118), and his subsequent issuing of an invitation sequence (data not shown) starting with a standard preinvitation (line 23) (see Haugh, 2009, pp. 104–7).

Although a standard Gricean account would make reference to the cooperative principle and conversational maxims in explicating these implicatures, such an account was never actually meant by Grice to constitute the basis of a formal psychological model for how hearers figure out what has been implied (or implicated in more technical parlance). Thus, while a distinction between default and *nonce* inference can be drawn in principle, the question remains as to what kinds of inferences are actually involved in generating these implicatures. A related question is how to account for the fact that such inferences may be revised in subsequent discourse due to their inherently defeasible nature, and, moreover, that different inferences may be drawn by different participants in the same interaction. The former question, relating to what types of inference underlie implicatures, has been tackled primarily by those working in cognitive–philosophical pragmatics (sometimes termed *pragma-linguistics*), including neo-Gricean theorists (e.g., Levinson, 2000) and relevance theorists (e.g., Sperber & Wilson, 1995). The latter issue, relating to the contingent and emergent nature of inferences, has primarily been the focus of scholars working within the sociocultural and interactional paradigm in pragmatics (sometimes termed *socio-pragmatics*).

Types of Inference: Cognitive–Philosophical Perspectives

Inference is a basic form of reasoning whereby we draw consequences that a proposition logically has when the truth of the first proposition guarantees the truth of further propositions (leading to entailments), or consequences that seem necessary, permissible, or reasonable for one to draw (leading to implicatures, among other things) (Woods, 2010, p. 218). The former type encompasses logical inferences that are not strictly open to error. The latter types of inference are generally characterized as defeasible, which means they always allow for the possibility of error. In other words, they may not seem necessary, permissible, or reasonable in certain situations. We can further distinguish between defeasible inferences that are monotonic and those that are nonmonotonic. Monotonicity refers to the property of inferences whereby the addition of new information does not reduce the set of what is known. In other words, no matter what further premises are added to a given premise set (provided none of the existing ones are erased), the set of conclusions can only increase. Nonmonotonicity, on the other hand, refers to inferences where their present reasonability may be lost upon the addition of new information. Examples (2) and (3), adapted from Carston (1995, p. 224), nicely illustrate this difference.

4 INFERENCE AND IMPLICATURE

(2) Monotonic inference

Premises: All humans are fallible.
Cameron is a human.

Conclusion: Cameron is fallible.

(2') Premises: All humans are fallible.
Cameron is a human.

Additional premise: All humans need water to survive.

Conclusions: Cameron is fallible.
Cameron needs water to survive.

(3) Nonmonotonic inference

Premise: Cameron has eaten three of the cakes.

Conclusion: Cameron hasn't eaten four of the cakes.

(3') Premise: Cameron has eaten three of the cakes.

Additional premise: If Cameron has eaten three of the cakes, he's bound to have eaten more.

Revised conclusion: Cameron may have eaten four of the cakes.

In the case of example (2), we can see that the addition of a new premise does not negate the previously drawn conclusion, but rather only augments the set of conclusions (as seen in [2']). However, in the case of example (3), the addition of a new premise does indeed negate the initial conclusion (as seen in [3']).

Deductive inference is generally considered monotonic, while inductive and abductive inference are generally considered nonmonotonic, although the former can also be deemed nonmonotonic when considered from the perspective of soundness as opposed to validity (Woods, 2010, p. 219). All three types of inference, namely, deductive, inductive, and abductive inference, have been called on by various scholars to explain how implicatures are calculated.

Grundy (2008), for instance, argues that an implicature is recovered through inductive inference on Grice's account, and so it constitutes "a probabilistic conclusion derived from a set of premises that include the utterance and such contextual information as appears relevant" (Grundy, 2008, p. 102). Others have claimed that the recovery of conversational implicatures is better accounted for through appeals to abductive reasoning (i.e., inference to best explanation; Allot, 2010), or its formal analogue, inference to best interpretation (Atlas, 2005). The key difference between inductive and abductive inference is that the former involves reasoning "from particular instances to a general hypothesis," while the latter involves reasoning where "the conclusions are based on a best guess" (Allan, 2006, p. 652).

Somewhat controversially, Sperber and Wilson (1995) proposed in earlier work that deductive reasoning is central to the recovery of implicatures (but see Carston, 2002). They suggested that implicatures can arise, for instance, through deductive inferences drawing from the speaker's original utterance along with additional premises sourced from encyclopedic information. One key problem with a reliance on deductive inference in recovering implicatures, however, is how to establish the closed set of propositions required for strict deduction. There is no solution given in relevance theory as to how the hearer decides

which premises to include and which to exclude, except by the circular argument that the premises selected are determined by calculations of relevance (roughly defined as positive cognitive effects relative to processing effort), which in turn determines what the hearer understands to have been implied by the speaker (Cummings, 1998). The circularity of such an approach arises from the fact that calculations of the relevance of the contextual premises are determined by the hearer's calculations of the relevance of what is implied.

While debates continue about the utility of these traditional types of defeasible inference in understanding implicatures, it has become increasingly apparent that other types of inference are also required to fully account for the generation of implicatures, including, according to Cummings (2005), elaborative and presumptive inferences. Elaborative inferences are knowledge-based inferences used to "establish causal connections between events and construct intentional relations between actions within reasoning," with this knowledge often involving "behaviour tendencies and everyday routines" that serve "to specify normality or typicality conditions on inference" (Cummings, 2005, pp. 91–3). The following example illustrates this claim.

(4) A: I'm out of milk.

B: There's a shop at the end of the street. (Cummings, 2005, p. 102)

In order for A to understand that B is implying that A can get milk from the shop at the end of the street, real-world knowledge is required, namely, that corner shops stock commonly used groceries, including milk. In other words, this implicature cannot be recovered without recourse to an elaborative inference involving (stereotypical) real-world knowledge.

Presumptive reasoning is also arguably crucial to the recovery of implicatures, since implicatures are almost always subject to revision based on the addition of further contextual information, but are nevertheless often held to be communicated, at least provisionally, by hearers. One kind of presumptive-reasoning system proposed by Cummings is "argument from ignorance," where a proposition is accepted as true because there is no evidence that it is not true (or vice versa) (Cummings, 2005, p. 109). On this view, then, presumptive and elaborative inferences are processing "shortcuts" that are "grounded in experience and associative links" (Capone, 2011, p. 1748).

The move to consider these other types of inferences in the interpretation of implicature, however, indicates an important change in our conceptualization of inference, namely, seeing them as arising relative to *contexts* rather than locally computed (Jaszczolt, 2005; Horn, 2009; see also Levinson, 2000). Such a move thus suggests that there needs to be more attention paid to emerging sociocultural and interactional perspectives on inference.

Sociocultural and Interactional Perspectives on Inference

One key criticism of cognitive–philosophical approaches to inference is that they have placed too great a burden on global reasoning processes without proper consideration of the manner in which inferences are situated in, and contingent on, the interplay of participants' utterances and understandings of those utterances in interaction. As Knippen (1995) has argued, our understanding of inference and its role in generating implicatures needs to be "restructured to reflect the extent to which more restricted mechanisms and processes sensitive to local cues guide the interpretation of language in conversation" (p. 127). It was noted in discussing example (1), for instance, that Steve's understanding of what was implied by Cameron's initial utterance in the excerpt depended on shared knowledge about the interpretation of that utterance-type among friends (i.e., it was situated), and that it changed in light of Cameron's subsequent utterance (i.e., it was contingent).

The claim that inference is situated, and thus sensitive to elements of both local and broader societal contexts, has been made by a number of scholars working in different paradigms. Gumperz (1982), for instance, argues in advancing his notion of conversational inference that interpretations are “situated or context-bound,” a point that is echoed by Bilmes (1993), who also suggests that implicature may involve “uniquely cultural understandings.” In the following exchange, for example, there is a (cultural) assumption that having sex before marriage is not only desirable but also permissible.

- (5) (One teenage boy asks another after B has had a date with a girl)
 A: What did you get?
 B: I kissed her.

In order for A to infer that B is implying that he did not have sex with the girl, A must make recourse to particular (cultural) knowledge about what can happen on dates (at least in some parts of the world). To treat inferences as situated is to recognize that implicatures are informed by “sociocultural knowledge and currently negotiated common ground” (Marmaridou, 2000, p. 248), or by “social regularities” in their interpretation (Mazzone, 2009, p. 344).

The claim that inference is contingent has also been advanced in a number of studies that have examined the ways in which meanings arise in actual interactional data (as opposed to constructed examples; Bilmes, 1993; Arundale, 2008; Haugh, 2008, 2009; Hirsch, 2010). One key finding has been that implicatures cannot necessarily be traced analytically to the prior intentions of individual speakers (including their communicative intentions). This is because participants reciprocally afford and constrain interpretations of implicatures by the adjacent placement of subsequent utterances, through which they display their understandings of the interactional import of prior and forthcoming utterances. In example (1), for instance, we can see how the response of the recipient (Steve) helps constrain what is implied among the potential interpretations initially afforded by the speaker’s (Cameron) first utterance, an understanding which is subsequently qualified by the first speaker (Cameron). Approaches that conceptualize the inferential work underlying meaning and communication as contingent and nonsummative (Arundale & Good, 2002; see also Haugh, 2009) thus arguably deserve further consideration in analyses of implicature. In this way, we may start to really address the fundamental problem of how speakers and hearers come to joint understandings (or diverging understandings) that something has indeed been implied in actual interaction.

Information Retrieval for Reading Tutors

MAXINE ESKENAZI AND ALAN JUFFS

Reading tutors are one example of an intelligent tutoring system. Such intelligent tutors seek to integrate content knowledge and instructional principles with models of an individual learner's knowledge and beliefs. In this way, an intelligent tutor can provide individualized instruction appropriate to the stage of development of the learner in the targeted knowledge domain. In this context, the use of information retrieval (IR) for reading tutors is relatively recent (Brown & Eskenazi, 2004) and stems from the strong desire on the part of language educators to give students practice in a realistic environment that goes beyond second language textbooks. In this case, the realism is provided by the authentic texts that are retrieved from the Internet. An authentic text is a text that has not been created or edited specifically for a (second) language learner. The challenge in using authentic documents to teach reading and vocabulary is that, unlike documents prepared by teachers expressly for their students, the materials typically obtained from the Internet are not homogeneous in content and in difficulty. This means that a simple search, containing one or several words and using a common search engine such as Google, will not retrieve documents that are satisfactory for use in tutoring. To find usable documents, the content of the Web pages that are found must be filtered, annotated, and presented to the student in an appropriate environment.

Intelligent computer-assisted language learning (ICALL) instruction in reading and vocabulary rests, first, on a body of research that has established the words students need to know from word frequencies in extensive spoken and written corpora (Nation, 2001). Second, instructional activities stress student *interaction* with online materials, either mediated by an online workbook (Zapata & Sagarra, 2007) or with some interlocutor (Smith, 2004). Activities that promote frequent exposure and deeper processing are also thought to be more beneficial (Laufer & Hulstijn, 2001; Folse, 2006). Reading and vocabulary tutors' ability to provide immediate, individual feedback and training has been shown to be helpful in promoting long-term retention of vocabulary items practiced through CALL (computer-assisted language learning). Finally, optimal spacing of practice sessions with intelligent tutors has also been of interest (Pavlik & Anderson, 2005) and should be incorporated into instructional programs in ICALL. (See Goodwin-Jones, 2010, for an overview of recent developments.)

Before beginning to develop instructional activities that reflect the considerations just discussed, three major processes are followed when using IR for reading tutors. First, there is a process to choose documents: finding them, filtering them, and annotating them. Second, there is a process to choose documents for an individual student: modeling the knowledge of the student and defining what they need to learn. Finally, there is a process for correctly presenting documents to students in a pedagogically meaningful manner. When these processes are implemented, the documents and the way they are presented succeed in serving a student's needs and the learning goals, rather than dictating them. A specific case of a reading tutor is the reader-specific lexical practice program (REAP) developed at Carnegie Mellon University (<http://reap.cs.cmu.edu/>); its development was

guided by the process described in the following paragraphs. Illustrations are provided from the REAP tutor.

Choosing Documents

A simple search of the Internet for documents may retrieve many Web pages that are useless for a student who is learning to read. For example, a teacher may look for documents that are on a topic that can spur much classroom discussion, such as “the death penalty.” A simple search for this expression will return many different sorts of documents. Some will be legal documents with terms and specific syntax that make it hard for the learner to understand the document. Others will be lists of addresses to Web pages that concern the topic: those lists, in themselves, are readable. Yet others will contain many unknown words, again making the document hard to understand. To avoid these issues, obtain pertinent documents, and avoid a long search through many Web pages, it is better to not directly use a search engine, but rather to search for documents, filter them, and shape them into a usable database.

Searching for Documents

The search is set up on a server that is fast and has sufficient memory to store many documents that may contain images. While it is possible to simply store the documents for as long as it takes to process them and then just keep their Web address (URL) and the annotations resulting from the processing, Web pages change and disappear constantly, so with memory being relatively inexpensive, it is better to store the entire Web pages that have survived the filtering process.

Searches are “seeded,” that is, they are given a set of URLs to start with. They collect the Web pages at those addresses and then follow all of the links that are on those pages, also collecting the linked pages. They then follow all of the links on the second set of pages, collect those Web pages, and so on. This can be continued until a set of a certain number of Web pages, say 50 million, is collected. This creates a database of material that can be accessed at runtime for the student in place of a direct Web search. A Web search could be performed in real time as the student waits, but if this is done, given that the search is looking for a document with very specific characteristics, this could take a long time. There are also some institutions that do not allow direct access to the Internet from their computers. It is generally accepted that the “offline” creation of a database, that is, before a student starts to use a reading tutor, is preferable. The number of documents to collect is variable according to need. In general, given the filtering process described below, somewhere between 1 and 5 out of 1,000 documents is kept at the end of the whole filtering process. There must be a sufficient number of documents remaining in the database after filtering so that selection can operate according to topic, word content, or level.

The search can be performed separately from document filtering, but this means that a very large number of documents must be kept in the system until filtering can be carried out. It is therefore often useful to run the search and feed the documents immediately into the filters so that both processes are carried out in parallel.

Filtering Documents

When a very large set of Web pages has been collected, they must be filtered for cohesion, for readability, for topic, for objectionable words, and for target word content. The last

criterion, target word content, assumes that, like many approaches to teaching reading, the tutor will be teaching vocabulary as the essential means of improving reading skills (Perfetti, Landi, & Oakhill, 2005; Perfetti, Wlotko, & Hart, 2005).

Since Web pages can be simple lists, or incoherent text, the first filter is aimed at eliminating anything that is not a cohesive text and it is responsible for most of what is eliminated. It is possible to use a parser for this task (Heilman & Eskenazi, 2006). In this case, the parser will give a score as to how well each sentence in the document has parsed (that is, corresponded to a string of words or parts of speech that is regularly observed in the language). By combining the scores of all of the sentences in a document into one overall parser score and determining a threshold for the parser score (after examining typical acceptable and nonacceptable Web pages), and retaining only the Web pages that are above that threshold, Web pages with poor text are eliminated. It is also possible to use measures of cohesiveness such as Coh-Metrix (Graesser, McNamara, Louwers, & Cai, 2004; Coh-Metrix, 2009) instead of a parser for this task. The term "Web page" has been used so far since the contents up to this point are not necessarily coherent documents. Now that this filtering is passed, we can use the term "documents."

Another issue that must be addressed in finding appropriate documents for each individual student to read is that some good, cohesive documents are difficult to read because they contain vocabulary or grammatical constructs (the latter especially in the case of non-natives) that the student has not yet learned. It is therefore desirable to annotate the documents as to their level of readability. Rather than eliminating documents, this process tags them as to level (K-12, for example), and thus enables the intelligent tutoring system to find documents that are at just the right level of difficulty for the student. Readability filtering can be accomplished by making a statistical representation of the words in the document (Collins-Thompson & Callan, 2004) or by using a representation that combines knowledge of both words and syntactic constructs (Heilman, Collins-Thompson, Callan, & Eskenazi, 2007). In general, a collection of sample documents that have been classified at the target levels by some criterion is used to construct the statistical models so that a new incoming document can be compared to these models.

After determining readability, documents can be annotated as to the topic that they address. Again, this process does not reduce the number of documents. Allowing students to choose documents on the topic of their choice is useful because it has been found that students learn better when they are reading something that they are interested in (Heilman, Juffs, & Eskenazi, 2007; Heilman et al., 2010). A set of topics is predetermined and a collection of documents on the topics to be annotated is assembled. An incoming document is compared to this, usually using a comparison of vocabulary content. The students are given a checklist of topics when they begin using the reading tutor and their choices are saved and matched with corresponding documents. Figure 1 is taken from REAP and provides a list of topics available.

The next step in the filtering process does eliminate documents. It is a search for objectionable words and expressions. It usually employs a handmade list. In addition to specific words, it is possible to block specific URLs or groups of them. For example, when teaching non-native students from certain countries, religious references have been found to be offensive and sets of URLs can be added to a "do not use" list.

The next process is again not intended to eliminate documents, but to classify their contents. As most reading tutors concentrate on teaching new vocabulary, this step finds words and annotates the documents for the words that they contain. Using either a handmade list of target words that the students should learn, or some generally accepted list such as the Academic Word List (Coxhead, 2000), each document is annotated with the words in this list that it contains and the frequency with which each word occurs in the document. Eventually, the words that have more than one meaning should also be annotated

Figure 1 Screenshot from the reading tutor called “REAP” (<http://reap.cs.cmu.edu/>) showing a reading topic checklist

as to which of the meanings is used in the document (Kulkarni, Heilman, Eskenazi, & Callan, 2008). In this way, the student can learn new meanings. Also, if there are post-reading questions, the meaning of the word in the questions can be matched to the meaning of the word in the document. This implies that there is a set of questions of some sort that are also annotated as to the meaning of the word.

Creating a Database of Documents

The documents that remain after filtering have a series of annotations (parser score, list of words, readability level) in some easy-to-access format for the intelligent tutor. The tutoring system is created in a way that enables rapid access to the document labels and the documents themselves. In general, once the intelligent tutor has found a candidate document to present to the student (it will find several in order to give the student the choice of what they want to read), it will also obtain something about the document to show the student so that he or she can make their choice. This can be the first few sentences or first 100 words of the document. More advanced systems may automatically summarize the contents of each document; that summary is kept as another annotation of the document and presented to the student when they are choosing the documents. Summarization is

still an error-prone process and so the use of snippets from the beginning of the document has been preferred.

It should be noted that this process is language independent and thus can be used for any language where a significant number of documents can be found on the Internet. The REAP system, for example (Heilman, Collins-Thompson, Callan, & Eskenazi, 2006), was created in English and subsequently other versions have been made for French and for European Portuguese (Marujo et al., 2009).

Intelligent Tutoring: Choosing the Right Document for a Specific Student

In order to choose the right document for a student to read, the intelligent tutor must possess information about the documents (as they have been annotated in the processes above) and have a model of what the student knows. The system must therefore be provided with a student model that represents the individual student's word knowledge when the student begins, and that changes while he or she uses the tutor. This model may be initialized by entering the level of the student (say fifth grade). The system can then automatically load a set of words that the student is presumed to know. However, the best way to initiate the student model is to have each student take a pretest that attempts to determine their vocabulary knowledge (at least for the target words). There can be many different types of questions, cloze type being the most frequently used (Pino, Heilman, & Eskenazi, 2008). It has, however, been found (Heilman, Zhao, Pino, & Eskenazi, 2008) that simply asking students whether they know a word may be just as effective in some cases. It was found that when a student said they did not know a word, there was a close correspondence with their performance for that word on cloze questions. On the other hand, there was no correspondence for words that the student said they did know. This result is useful for two reasons: first, it enables the system to present many words in little time for the pretest. Second, it enables the intelligent tutor to know which words the student does not know and thus to concentrate on finding them first in the documents.

Once the intelligent tutor has presented documents to the student and the student has chosen a document to read, the intelligent tutor can update the student model in one of two ways. The simplest way is to just increase the value of knowing a word by some measure for each word that is in the document that the student is reading. A better way is to present the student with post-reading questions and to use the scores from their performance on those questions to update the student model.

A system can automatically create cloze questions (Pino et al., 2008) and, since it can generate them, it can also score the answers to them. When teachers are presented with automatically generated cloze questions, they generally accept about 65% of them as being useful. Therefore, present practice uses a fixed set of target words with a fixed, manually generated set of cloze questions, about 5–10 cloze questions per word, per meaning. The questions are annotated with the meaning of the word if it has several, and they are randomly selected for presentation.

Presenting Documents for Use by Students and Teachers

There are several scenarios of how an intelligent tutor for reading that uses IR can be employed. They range from a teacher's use in search of a document to use in class without the tutor, to group use of the tutor, to individualized use of the tutor.

In some cases, a teacher may simply be looking for a document to be used in class either to be read on paper or to be accessed directly through its URL. As in the case of the unfiltered

documents above, the teacher may have to spend an inordinate amount of time searching through documents that a search engine found for “the death penalty” for one that can be used. However, if the tutoring system can be used as a search engine, then the teacher can input “the death penalty,” “reading level 6,” and words = “review,” “inaccurate,” “legal,” to find an appropriate, coherent document much faster.

If the teacher has a computerized classroom, then they may want the students to all read the document within the tutoring system. One same document can be presented to the whole class and post-reading questions can follow. There can also be a set of pre-chosen documents that the students can read later at their own pace.

Finally, students can use a tutor of this kind to read on their own with documents that the intelligent tutor automatically selects according to the procedures described above. In this case, it is useful to give the students help as they are reading the document. There are several types of help that can be used. First, the post-reading questions can be of help to the student by, once their answers have been recorded, giving them the answer to the question, so that they can immediately learn something about a word. While the student is reading a document, there are several types of help that can be used. First, seeing a definition of a word may help them. For this, they can open a separate window on their computer and use an online dictionary, as illustrated in a screenshot from REAP in Figure 2.

If, however, there is some reason for the tutor to track the words they have looked up, then it is preferable to embed a dictionary in the system itself. Here again, if a word has several meanings the meaning in the definition that is shown should in some way be

Figure 2 Screenshot from the reading tutor “REAP” (<http://reap.cs.cmu.edu/>) showing target vocabulary words

made to match the meaning of the word in the document. Another type of help is to show examples of a chosen word in other sentences. The system can also use either recorded speech (for a small, predetermined set of words) or speech synthesis in order for the student to be able to hear the word, since some words may be known aurally, but not visually. Finally, the tutor can permit the student to look up any unknown word or word he or she is unsure of. This feature can assist the student and inform teachers if they are overestimating students' knowledge of common words.

Helpful Additions to a Tutor

It has been observed that a good tutoring system will also count the number of presentations of each word, favoring several presentations of each word over just one presentation of many words in optimal spacing for long-term retention (Pavlik & Anderson, 2005; Cobb & Horst, 2011). Other aids that make learning with a tutor of this kind more effective are "use this word in a sentence" questions. This type of question cannot at present be graded automatically and so requires the blended participation of a teacher. But the time invested by the teacher is gained back by better learning since this form of question requires the most active (sentence creation) participation of the student.

It is also helpful to allow the student to have access to the system outside of assigned class time. Allowing students to search for interesting documents encourages more time on task, which has been shown to improve learning. Also, as mentioned above, it is desirable to keep the images in the documents. These add interest and often aid in understanding a text. Students using the tutor are accustomed to the advanced graphics of Web documents, and will expect the same from the tutor's offerings. Finally, it has informally been observed that the way that the teacher reacts to using the tutor (presenting it as a great aid or as a nuisance) has a great effect on student participation and thus on learning. A reading tutor using information retrieval should be seen as an extension of teacher time and as an aid. It should represent a saving of time and not require significant effort to include in a class. And, as a way to monitor student knowledge through direct access to the student model, it should enable a teacher to keep better track of each and every student's progress.

Information Structure

JEANETTE GUNDEL

Introduction

Natural languages offer speakers a variety of options for expressing the same basic informational content. For example, in English, the sentences in (1a)–(1i) below can all be used to convey the information that a person named Sally won a contest.

- (1) a. Sally won that contest.
- b. The contest, Sally won.
- c. There was a contest that Sally won.
- d. This contest was won by Sally.
- e. She won a contest.
- f. It was Sally who won the contest.
- g. What Sally won was the contest.
- h. (As for) that contest, Sally won it.
- i. She won the contest, Sally.

The possibilities can be further multiplied by placement of a prominent pitch accent on different constituents of these sentences.

The term “information structure” has been used to refer to the kinds of distinctions exemplified by the sentences in (1), both at the level of meaning and at the level of morpho-syntactic and prosodic form used to express that meaning. It is widely assumed that these options reflect different ways that information expressed in a sentence is conceptualized, depending on (a) the entity that the utterance is primarily about, as distinct from new information asserted, questioned, and so forth about this entity; and (b) assumptions about the addressee’s knowledge/memory and attention state. Such factors provide the basis for explaining why the sentences in (1) cannot be used appropriately in the same context.

Work on information structural concepts within the Western grammatical tradition can be traced back to at least the second half of the 19th century. The German grammarians Gabelentz (1868) and Paul (1880) used the term “psychological subject” for what is now called topic, ground, or theme, and “psychological predicate” for what is now called comment, focus, or rheme. Work by the Czech linguist Mathesius in the 1920s (e.g., Mathesius, 1984) initiated a rich and highly influential tradition of research in this area within the Prague School that continues to the present day. Also influential has been the seminal work of Halliday (1967) and, within the generative linguistic tradition, Chomsky (1971), Gundel (1974), Kuno (1972, 1976), Kuroda (1965), Reinhart (1981), among others. More recent work is cited below.

The next section addresses the question of what kinds of phenomena are included under the term “information structure.” It is followed by a section that provides a brief overview of how information structure is formally expressed across languages.

What Is Information Structure?

The term “information structure,” originally introduced by Halliday (1967), has been widely associated with the distinction between given and new information expressed in a sentence. There continues to be disagreement and confusion, however, regarding the exact nature of information structural primitives themselves, and their relation to one another. Some of the confusion has resulted from conflating two distinct types of givenness/newness. Following Gundel (1988), these are described as “referential givenness/newness” and “relational givenness/newness.” The terms “information structure” and “information status” have been used interchangeably by many authors for both concepts and both will therefore be discussed here.

Referential Givenness/Newness

Referential givenness/newness involves a relation between a linguistic expression and a corresponding nonlinguistic entity in the speaker/hearer’s mind, the discourse (model), or some real or possible world, depending on the analyst’s assumptions about where the referents of these linguistic expressions reside. Some representative examples of referential givenness concepts include various senses of referentiality and specificity, the familiarity condition on definite descriptions (e.g., Heim, 1982), the activation and identifiability statuses of Chafe (1994) and Lambrecht (1994), the hearer-old/new and discourse-old/new statuses of Prince (1992), the levels of accessibility of Ariel (1990), and the cognitive statuses of Gundel, Hedberg, and Zacharski (1993). For example, the cognitive statuses on the Givenness Hierarchy in Table 1 represent referential givenness statuses that an entity mentioned in a sentence can be assumed to have in the mind of the addressee.

The Givenness Hierarchy (Gundel et al., 1993)

in focus	activated	familiar	uniquely identifiable	referential	type identifiable
<i>it</i>	<i>this N/this/that/SHE</i>	<i>that N</i>	<i>the N</i>	<i>indefinite this N</i>	<i>a N</i>

Note. *SHE* here represents all stressed personal pronouns. Uppercase letters here and elsewhere in the entry indicate location of a prominent pitch accent.

Gundel et al. propose that determiners and pronouns across languages signal these cognitive (memory and attention) statuses as part of their conventional meaning. The relevant English forms are listed here below each status. A speaker’s assumptions about the status of some entity in the mind of the addressee thus constrain the forms that may be appropriately used in referring to that entity, and the lexical items in question provide information as to how or where the intended referent can be mentally accessed. Since the statuses are in a relation of unidirectional entailment (i.e., each status entails all lower statuses on the hierarchy, but not vice versa), lexical items provide increasingly more specified information about cognitive status as one moves up (from right to left) on the hierarchy. For example, in (1e), the indefinite article *a* informs the addressee that he or she is only expected to access a representation of the type of thing described (type identifiable), which should be possible just in case the addressee understands the meaning of the word *contest*; the definite article *the* in (1b) and (1i) instructs the addressee to associate a unique representation of a specific member of that type (uniquely identifiable); the demonstrative determiner *that* in (1a) provides the information that the intended referent is to be accessed by selecting a representation that already exists in memory (familiar); the demonstrative determiner *this* in (1d) provides the information that the intended referent is to be associated with an

entity in current awareness (activated) and the pronoun *she* in (1i) provides the information that the intended referent is not only in awareness, but in current focus of attention. The relation of unidirectional entailment that holds between statuses also gives rise to implicatures which result from interaction of the Givenness Hierarchy with general pragmatic principles (Grice, 1976; Sperber & Wilson, 1995). This includes, for example, the implicature that the interpretation of an indefinite article phrase is at most referential, that is, not uniquely identifiable, familiar, and so forth (see Gundel et al., 1993). Referential givenness concepts have also been shown to play a role in such linguistic phenomena as sentence accent and word order. Greater degrees of referential givenness are associated with weaker stress (see, e.g., Ladd, 1972; Chafe, 1994; Lambrecht, 1994) and also with right attachment/dislocation, as in (1i) above (Gundel, 1988; Vallduví, 1992).

Relational Givenness/Newness: Topic–Focus Structure

Relational givenness/newness involves a partition of the semantic-conceptual representation of a sentence into two complementary parts, X and Y, where X is what the sentence is about and Y is what is predicated about X. X is given in relation to Y in the sense that it is independent and outside the scope of what is predicated in Y. Y is new in relation to X in the sense that it is new information asserted, questioned, and so forth about X. For example, (1a) above may be used to describe a particular event of a person named Sally winning a contest, from the perspective of Sally, where Sally is what the sentence is about and what is predicated about Sally is that she won a particular contest that is already familiar to the addressee. The same event may be described from the perspective of the contest, as in (1d) or (1h), where the contest is what the sentence is about and what is predicated about the contest is that Sally won it. Terms used to denote relational givenness/newness concepts include psychological subject and predicate (e.g., in the works of Gabelentz and Paul mentioned above), presupposition–focus (e.g., Chomsky, 1971; Jackendoff, 1972), background-focus (e.g., Krifka, 2006), topic–comment (e.g., Gundel, 1974), and theme–rheme (e.g., Vallduví, 1992), among others. The term “topic” will be used here for what has variously been called psychological/logical subject, theme, and ground; and “information focus” will be used for what has variously been called psychological/logical predicate, rheme, and comment. The relational notion of information focus (as complement of topic) should not be confused with the referential notion “in focus,” which refers to the cognitive status of a discourse referent.

Referential and relational givenness/newness are logically independent, as seen in (2).

- (2) A. Who called?
- B. Pat said SHE called. (Gundel, 1980)

If *SHE* in (2) is used to refer to Pat, it is referentially given in virtually every possible sense. The intended referent is presupposed, specific, referential, familiar, activated, in focus, uniquely identifiable, hearer-old, and discourse-old. But it is at the same time relationally new, and therefore receives a focal accent here.

How Is Information Structure Formally Expressed Across Languages?

Information Structure and Prosody

An association between prosody and information structure has been shown to hold in a variety of typologically and genetically diverse languages, where the most consistent way of marking information structure is through placement of a prominent pitch accent within

4 INFORMATION STRUCTURE

the comment/focus (see, e.g., Gundel, 1988). Moreover, as illustrated in examples (3) and (4) below, assignment of prominent pitch accent to the relationally new, focal constituent overrides the weaker stress that is typically assigned to constituents with a high degree of referential givenness, that is, ones that are in focus or at most activated.

The crucial role that prosody plays in marking information structure is compellingly illustrated in the following example from Lambrecht (1994, p. 133).

(3) Nazis tear down antiwar posters

As Lambrecht notes, most people, when asked to interpret a written sentence like (3) in the absence of any contextual cues, would assign a prominent pitch accent to the direct object (antiwar posters), the default accentual pattern that people normally assume when presented with written sentences in isolation, yielding an interpretation where the topic and focus coincide with the grammatical subject *Nazis* and the grammatical predicate *tear down antiwar posters* respectively. Such an interpretation would be likely, for example, in a context where (3) is uttered during a discussion about Nazis. What is particularly compelling about this example is that, as Lambrecht points out, the interpretation of the sentence, as well as the accentual pattern we assign to it, changes dramatically when we are provided with the context in which he first encountered the sentence. Lambrecht notes that the sentence was “written with a felt pen across a poster protesting the war in Central America. The poster had been partly ripped down from the wall it had been glued onto.” Provided with this additional contextual information, the prominent pitch accent now shifts to the subject and the resulting interpretation, that people who tear down antiwar posters are Nazis, is truth-conditionally distinct from the one we assign to the sentence when prominent pitch accent is on the direct object.

A new or contrastive topic typically receives some sort of prosodic prominence as well, resulting in sentences with two prosodic peaks, as in (4b) below.

- (4) a. What about Fred, what did he do?
b. FRED ate the BEANS.

In languages like English and German, the pitch accent that marks information focus is distinct from the one that marks a contrastive topic. In English, for example, (4b) as an answer to (4a), would have a simplex high tone (H*) accent on “beans” and a complex, low followed by high (L + H*) accent on “Fred” (Pierrehumbert, 1980). But in response to a question like “What about the beans, who ate them?” *Fred* would have an H* accent and *beans* would have an L + H* accent. However, not all languages distinguish prosodically between information focus and a contrastive or newly introduced topic. Thus Fretheim (1992) argues that the pitch contours that encode contrastive topic and information focus in Norwegian are not distinct. For example, (5), with a prosodically prominent subject as well as a prosodically prominent direct object, could be a statement about Fred or a statement about the beans. There is no intonational phenomenon in Norwegian that enables the hearer to uniquely identify topic and focus in an utterance of (5).

- (5) FRED spiste BØNNENE
Fred ate beans.the
“Fred ate the beans”

Similarly, according to Vallduví and Vilks (1998, p. 89), information focus (their “rheme”) and contrast (their “kontrast”) are “associated with a single high tone accent” in Finnish; and the distinction between the two is coded syntactically rather than prosodically.

Information Structure and Morphosyntax

All human languages appear to have different syntactic constructions for describing the same event or state of affairs, depending on information structural concepts such as those discussed above. The structure most widely and consistently associated with syntactic encoding of relational givenness–newness is one where a constituent referring to the topic of the sentence is adjoined to the left or right of a full sentence comment/focus. Such prototypical topic–comment structures (also known as left or right dislocations), exemplified in (1h) above (*That contest, Sally won it*), are relatively unmarked in so-called topic-prominent languages like Chinese and Japanese (Li & Thompson, 1976). In some of these languages, for example Japanese and Korean, topic or focus may also be marked morphologically (see, e.g., Kuroda, 1965; Kuno, 1972; Gundel, 1988; Lee, 1999).

Languages differ, however, in the consistency with which information structure is directly mapped onto surface syntactic structure. For example, as noted in Chao (1968), the grammatical predicate of a sentence and what he calls the “logical predicate” (here “information focus”) frequently do not coincide in English. Chao illustrates this point with the following exchange between a guide (A) and a tourist (B).

- (6) A: We are now passing the oldest winery in the region.
 B: Why?

The source of the humor here is that the English sentence uttered by the guide has two possible interpretations. On one interpretation, the information focus coincides with the grammatical predicate, *are now passing the oldest winery in the region*. On the other interpretation, the information focus includes only the direct object, *the oldest winery in the region*. The tourist (B) seems to be questioning the first interpretation, but it is the second interpretation that the guide actually intended to convey. Chao notes that the humor would be absent in Chinese because the guide’s intended message would be expressed by a structure that more literally translates as “What we are passing now is the oldest winery in the region.” Thus, while the different syntactic constructions are available in both languages, Chinese more consistently exploits the syntactic option for directly mapping information structure onto syntactic structure.

Similar differences are found even among very closely related languages. For example, while cleft sentences such as those in (1f) exist in all Germanic languages, they are much more frequently used in Norwegian and Swedish than in English (Johansson, 2001; Gundel, 2006). Gundel (2006) proposes that this difference is due to a stronger tendency to map syntactic structure directly onto information structure in Norwegian and Swedish. Specifically, these languages exhibit a strong tendency to keep information focus out of subject position and to encode presupposed material as a single constituent in the subordinated cleft clause, for example, *who won the contest* in (1f).

Sentence structures like (1b) (*The contest, Sally won*), where an argument is displaced from its canonical position and appears sentence-initially, are also well suited to syntactic encoding of information structure, as they make the distinction between topic and information focus structurally explicit. But the specific mapping between the information structure and the syntax can vary. Thus the sentence initial constituent, *the contest* in (1b), may refer either to the topic (e.g., as an answer to “What about the contest?”) or to the information focus (e.g., as an answer to “What did Sally win?”) Corresponding to this distinction, the sentence-initial phrase would also have two different pitch accents in English. As noted above, however, this is not the case in Finnish or Norwegian, for example.

Similarly, a clefted constituent, for example *Sally* in (1f), typically marks the information structural focus, while the content of the cleft clause is presupposed and topical. (1f) would thus be an appropriate response to “Who won the contest?” In English, an utterance with

this interpretation would have a prominent H* pitch accent on the clefted constituent. However, cleft sentences like (1f) (and their counterparts in other languages) do not always have a single prominent pitch accent on the clefted constituent. The accent associated with information focus may also fall within the cleft clause. Hedberg (2000) argues that in such “all news” clefts, the information focus includes both the cleft clause and the clefted constituent, as in (7) below and the most prominent accent falls at the end of the cleft clause.

- (7) [Beginning of a newspaper article] It was just about 50 years ago that Henry Ford gave us the weekend. On September 25, 1926, in a somewhat shocking move for that time, he decided to establish a 40-hour work week (*Philadelphia Bulletin*, cited in Prince, 1978, p. 898)

Conclusion

Human languages differ in the manner and extent to which information structural concepts such as topic, focus, and various degrees of referential givenness are directly and unambiguously encoded by linguistic form (syntax, prosody, morphology, or some combination of these). However, it is generally agreed that information structure has important reflexes in the grammars of all human languages, and its expression and interpretation cannot be completely reduced to general pragmatic principles governing human interaction or to other cognitive/pragmatic abilities that are independent of language.

At the same time, however, it is evident that information structural concepts are pragmatically relevant categories with clear pragmatic effects, including the appropriateness/inappropriateness of sentences with different possibilities for information structural interpretation in different discourse contexts. The relevant question then is which information structural concepts and properties are purely linguistic and which are derivable from more general pragmatic principles that govern language use.

Inhibition and Control in Second Language Acquisition

DAVID W. GREEN

Acquiring a second language (L2) is a dynamic process. New word forms can change how concepts of even common household objects (such as “bottle”) map onto their referents in the physical world (e.g., Ameel, Malt, Storms, & Van Assche, 2009). New expressions can change the way events are conceptualized and causal statements are understood (e.g., Wolff & Ventura, 2009). The dynamic effects of L2 acquisition do not end there. Acquiring a second language exerts profound effects on the dynamics of speech production itself (Green, 1998). Understanding such dynamics is vital if we are to understand the process of L2 acquisition and speech performance in bilinguals.

Acquiring a second language challenges the process of speech production. How this challenge is met is the subject of experimental research and theoretical debate. A basic challenge concerns how a person acquiring an L2 avoids intrusions from their first language (L1). The words and concepts of the L1 are better known and more practiced. Indeed, initial acquisition may connect the words of L2 directly to translation equivalents in L1 (Kroll & Stewart, 1994). In consequence, when speaking in the L2, translation equivalents in the L1 may be active. How is a speaker able to select the words of L2 over those in L1?

Conceivably, given a direct link between concept and word in the L2, L1 words are simply blocked out or filtered out from the production process (e.g., Finkbeiner, Almeida, Janssen, & Caramazza, 2006). If so, there is no basis for predicting the conceptual changes noted above and no reason to expect intrusions from the L1 into the L2. However, words from the L1 do intrude, at least occasionally, and especially when proficiency in the L2 is low (e.g., Poulisse & Bongaerts, 1994). Such intrusions also appear more commonly in children than in adults and perhaps in older rather than in younger adults (Bialystok, 2001). This pattern suggests that both languages are active, even if only the L2 is intended, and that alternate expressions in the L1 and L2 compete to control speech production. Data from a variety of experimental paradigms tell the same story (e.g., Lee & Williams, 2001; Marian & Spivey, 2003). The pattern also intimates that frontal regions of the brain may be part of the mechanisms of speech control in bilinguals. Such regions develop slowly in childhood and are among the first to show age-related declines in efficiency (Craik & Grady, 2002).

On this view, language control recruits mechanisms external to the language system to resolve language conflict and interference (Green, 1998; Abutalebi & Green, 2007). On the assumption that exercise of such a mechanism improves its efficiency or capability (Bialystok, 2001), we can also account for the advantage bilinguals show in certain nonverbal tasks that require them to inhibit misleading information. Compared to their monolingual peers, bilingual children, young adults, and older bilinguals are less affected by distracting information (e.g., Bialystok, 2009).

The data also suggest that control of the system may change with proficiency in the L2 (Costa, Santesteban, & Ivanova, 2006). The links between concept and word form may strengthen. In addition, practice may make it easier to actually pronounce a word in the L2 (i.e., execute its motor program). Such changes may be expected to reduce the competitive effects of the L1 but do not guarantee their absence. Consider how the activation

of L1 may change during the course of a conversation in L2 when the speaker aims to be in a unilingual rather than in a bilingual mode (Grosjean, 1998). There will be cues to the L1 that may lead to a temporary increase in the activation of the L1. Such cues include the topic of the conversation, such as talk about a holiday taken in a country where the L1 is spoken, and linguistic cues, such as the use of a word similar in sound and meaning to one in the L1 (i.e., a cognate). Research looking at transient increases in control demands is in its infancy, but there is research on language switching that is helpful in understanding some of the mechanisms that are involved in language control and that are likely to be important in L2 acquisition. Such studies point to the important role of inhibition.

Consider a switching experiment in which speakers name single digits in either their L1 or their L2 on the basis of a color cue. A French–English bilingual speaker, for example, may be required on one trial to name a digit (e.g., 8) in English and then on a following trial to name another digit also in English (a non-switch trial) or to name it in French (a switch trial). Predictably, individuals take longer to name digits on switch compared to non-switch trials. However, what is remarkable is that they take even longer when the switch trial requires them to name in their L1 compared to their L2 (Meuter & Allport, 1999). Such a result suggests that in order to switch into their L2 in the first place they strongly inhibited their L1 and so switching back into L1 takes longer as naming must overcome the effects of such inhibition. This asymmetry in the cost of switching into L1 versus L2 disappears when proficiency is high in both languages (Costa et al., 2006). More recent work indicates that inhibition affects the language as a whole and not simply items in the category being named (Philipp & Koch, 2009).

If inhibitory processes play a role when individuals are switching between languages, what role might they play during the course of L2 acquisition? In a novel study, Levy, McVeigh, Marful, and Anderson (2007) asked participants to repeatedly name pictures either in their L1 (English) or in their L2 (Spanish). After this naming phase, participants had to produce an L1 word corresponding to one of the presented pictures that rhymed with a cue in L1. So, for example, a participant might be presented with a cue such as “break: s_____” where the intended target was “snake.” Levy et al. (2007) found that participants generated significantly fewer target words if they had named the picture in their L2 (e.g., saying “culebra” to a picture of a snake) compared to their L1. They interpreted their data as support for the notion that the sounds of words in the L1 are suppressed during naming in the L2 at least during the early stages of L2 acquisition when there is still a marked difference in the time to name pictures in the L1 and in the L2.

More dramatic effects might be envisaged when the L2 is acquired during study abroad. Immersion may restrict the competitive effects of the L1 and encourage a direct linkage between concepts and word forms in the L2. In the first experimental study of its kind, Linck, Kroll, and Sunderman (2009) examined the extent to which immersion aids L2 acquisition because it reduces the activity of the L1. Their results are consistent with this possibility. They contrasted the performance of young American university students learning Spanish in Spain with a matched group learning Spanish in the classroom in the United States. One linguistic task was translation recognition. A Spanish word was presented followed by an English word and participants pressed a “yes” button to indicate that the second word was a translation of the first or a “no” button to indicate that it was not. The word pairs included correct translations (e.g., “cara–face”) and distractors that required a “no” response. Two distractor conditions are pertinent. In the lexical-neighbor condition the English word was similar in visual form to the Spanish word (e.g., “cara–card”). In the semantic-neighbor condition, the distractor was related in meaning to the correct translation (e.g., “cara–head”). Each condition included its own control pairs that were incorrect translations unrelated in either meaning or form to the Spanish word or to its correct translation. The key data are the differences in reaction time between the distractor

trials and their controls. Most interestingly, compared to non-immersion learners, immersion learners rejected lexical neighbors more rapidly and semantic neighbors more slowly. Indeed immersion learners showed no interference in the lexical-neighbor condition. Overall, these data are consistent with the intriguing possibility that immersion learning facilitates L2 acquisition by inhibiting L1 and its word forms and emphasizing the semantic pathway from lexical concept to word form.

In conclusion, acquiring a second language involves mechanisms of language control. Such mechanisms are required to manage the competition between languages. Initially effective acquisition may be achieved at the cost of accessibility to L1 word forms or sounds. With an increase in proficiency, such mechanisms monitor and control the language of use. The detailed operation of these mechanisms and their neural substrate is an open field for 21st-century research.

Inner Speech in Second Language Acquisition

MARÍA C. M. DE GUERRERO

Though commonly associated with talking to oneself in silence, inner speech is a much more encompassing and consequential phenomenon than internal self-talk. Inner speech is a socially derived mechanism that makes possible verbal (symbolic) thought. Lev Vygotsky (1986), who may be considered to date the foremost proponent of a theory of inner speech, maintained that to understand verbal thought it was necessary to trace the development of inner speech to its ontogenetic precursors. Working within a socio-cultural-historical approach to cognition, Vygotsky (1986) saw the genesis of inner speech as the development of the capacity to “think words” (p. 230) silently. Children, Vygotsky claimed, start using language in a purely social fashion to communicate with others. However, through the process of internalization of sociocultural experience, at about school age children begin to use social speech to mediate mental functions. In this process, speech ceases to be merely social; it acquires psychological status; it becomes intellectual speech for the self.

The intellectualization of social speech entails not only a change in function but a transformation in structure, Vygotsky (1986) observed. As social speech turns into speech for oneself, first in the form of vocalized egocentric (or private) speech and subsequently inner speech, there is a gradual shedding of external traits: Audible vocalization is inhibited; expanded syntax turns abbreviated and elliptical; and, most importantly, semantic structures begin to operate on the basis of condensed, agglutinated, and idiosyncratic senses of words. For this reason, Vygotsky described inner speech as being “to a large extent thinking in pure meanings” even though “it still remains speech, i.e., thought connected with words” (p. 249). At times, however, inner speech may adopt a more expanded and elaborated form, for example, in the process of planning what we are going to say or write (Vygotsky, 1986, p. 243) or as we talk to ourselves (Vocate, 1994). What is important in inner speech, Vygotsky (1986, p. 244) argued, is semantics, not phonetics. Semantically, Vygotsky pointed out, inner speech relies on *sense* (*smysl*)—all the fluid, dynamic, and personal evocations of a word that arise from its multiple contexts of use—rather than *meaning* (*znachenie*), the more definite and stable senses of a word, such as those fixed upon in dictionaries.

Inner speech develops as a consequence of internalizing a culturally specific system of signs and communicative practices. For people who grow to speak only one language, this process ultimately results in primary language (L1) inner speech, or inner speech mediated by meanings acquired through the L1. The acquisition of one or more additional languages is, however, a normal phenomenon for many people at any chronological age. What happens, then, when a language additional to the L1 is learned? A host of questions come to mind when inner speech is looked at from a second language acquisition (SLA) perspective: What is the nature of the inner speech of people who have acquired or are acquiring one or more L2s? Can inner speech mediated by the L2 evolve from the acquisition of L2 social speech? What role does the L2 play in mental functioning? Can an L2 mediate thinking the way an L1 does? And, can instruction influence the development of L2 semantically based inner speech?

2 INNER SPEECH IN SECOND LANGUAGE ACQUISITION

One route for the study of inner speech among L2 learners has been through the observation of the audible private speech vocalizations learners produce when engaged in L2 verbal tasks. This approach follows Vygotsky's genetic method, that is, the notion that higher psychological functions should be studied in their formation. In this view, inner speech can best be understood when examined through its developmental forerunner: egocentric (private) speech. A study by Centeno-Cortés and Jiménez (2004), which followed this line of research by examining the externalized private thinking processes of Spanish-L2 learners, revealed that advanced proficiency participants could use the L2 for reasoning purposes more than intermediate ones, yet resorted to the L1 when the cognitive task became too challenging, a finding that suggests that, when it comes to certain complex mental operations, the L1 might be a more effective tool than the L2 to mediate thinking.

Rather than focusing on private speech, some research has addressed the internal—though not directly observable—manifestations of inner speech in SLA. Ushakova (1994), for example, reporting an experimental project involving learning new words from an artificial language, concluded that the influence of inner speech semantic structures acquired through the L1 “can rarely, if ever be completely eliminated” (p. 136) in L2 acquisition. Other studies relying on self-report data (Guerrero, 1994, 1999, 2004; Gutiérrez, 2000), as well as research on verbal thought, bi/multilingualism, and L2 neurolinguistic processes (see review in Guerrero, 2005, chap. 3), suggest that, given certain conditions of language learning, it might be possible—though not easy—to develop inner speech based on an additional language beyond the L1.
